"""Console rendering for the pipeline. Printing and logging only.

SELF-CONTAINED BY DESIGN
========================
Presentation constants (bar glyphs, colours, widths, stamp format) live
HERE, not in zowe_rules. The previous version imported them from the
rules module, which owns mainframe facts - artifacts, libraries,
diagnostics - and knows nothing about a terminal. That coupling failed
at import time the moment a glyph name was missing.

Only STATUS_* and NAME_* are imported, because those are shared FACTS
that zowe_pipeline_steps.py and zowe_env.py also read.

PUBLIC API - unchanged, do not shrink it:
    banner, footer, section, header, row, bullets, warnings,
    step_start, step_line, summary, verdict,
    credentials, configure_logging, logger
`zowe_commands.py` imports bullets/credentials/header and
`zowe_pipeline.py` imports configure_logging/header/logger/summary.

# LOCATION: zowe/zowe_manifest.py
# ACTION: CREATE NEW FILE
"""Per-execution program manifest for monitoring.

For every IDMS program in the workspace Program folder this writes ONE
timestamped monitoring file into the Review folder, mapping the program
to the copybooks, DCLGENs and subschema it references, plus the derived
DB2 PROGRAM-ID:

    IDMS Program - Copybook - DCLGen - Sub Schema - DB2 Program
    VM4BD420 - ESDATMAS - DZBEFFTV, DZEVEFTV - VMBTS07 - VMDZ4420

Dependencies are resolved from each program's own source (the same
resolver the fetch step uses), so the file reflects exactly what was
fetched for that particular program. It never raises for a business
condition - a program that cannot be read is simply skipped.

"""Reads meaning out of a runner's console output.

The pipeline launches each runner as a SUBPROCESS, so its stdout IS the
contract. This module turns that text into a small dict of facts the
console can render in six lines instead of four hundred.

PATTERNS LIVE HERE, DELIBERATELY
================================
Project convention puts regex in zowe_patterns.py. This module is the
exception: every pattern below matches ONE runner's wording and has no
other consumer, so splitting it across two files would mean two places
to edit whenever that wording changes. No program, record, table or
column name appears in any pattern.

Every fact is OPTIONAL. A value that cannot be found is 0, empty or
None, and never raises.

"""Regex for the cursor close-guarantee pass.

Regex only. No rules, no constants, no names, and - deliberately - NO
project import of any kind.

CORRECTION - circular import
----------------------------
This module previously re-used patterns from a sibling pattern module.
The sibling imported back, so the first consumer to request a name while
this module was still executing failed with

    ImportError: cannot import name 'CONTINUE_PATTERN' from partially
    initialized module 'patterns.cursor_close_guarantee_patterns'

The defect was latent for as long as CursorCloseGuaranteeComposer was
never constructed. Registering the composer made the path live and the
cycle immediate. `import re` is the ONLY import this file may ever hold.

A COBOL paragraph name may begin with a DIGIT: every generated cursor
paragraph is numbered (710-OPEN-<cursor>). A pattern requiring a leading
letter makes the whole generated block invisible.

# LOCATION: patterns/db2_date_patterns.py
# ACTION: REPLACE ENTIRE FILE

"""DB2 date comparison regex patterns.

These patterns support conservative DB2 date realignment before comparing
DB2 date host fields with COBOL numeric date fields.

CORRECTION 1 - the host had to be the first token after IF
----------------------------------------------------------
DB2_DATE_COMPARISON_PATTERN was anchored as

    ^\\s*IF\\s+(?:DA|DT)-...

so it matched only a bare single-operand IF. A parenthesised or compound
condition such as

    IF (DA-CPTAFS-479BFAS OF DCLDZBFASTV < DA-ARCH-YMD
       AND DA-CPTAFS-479BFAS OF DCLDZBFASTV NOT = '00000000') OR

never matched, the detector returned an empty field list, and the whole
pass was skipped in silence.

CORRECTION 2 - a business field name was hardcoded in patterns/
---------------------------------------------------------------
The old condition group was

    (?P<condition>.+\\bPARMDATE\\b.*)

PARMDATE is a host variable belonging to ONE program. rules/authority_rules
forbids hardcoding host variables anywhere, and any program comparing a
```

```
DATE host against a differently named field was silently skipped. The
comparison operand is no longer named; a DATE host is now recognised by
its DCLGEN-qualified shape alone.

CORRECTION 3 - multi-line conditions
------------------------------------
Matching is performed against an ASSEMBLED logical condition, not a single
physical line. Db2DateConditionAssembler owns the assembly.

Regex only. No rules, no constants, no program / record / table / DCLGEN /
host variable names.

"""COBOL fixed-format sequence handling.

CORRECTION 1 - the indicator column was required to be blank
------------------------------------------------------------
The original left-sequence pattern demanded whitespace after the six
digits:

    r"^\\s*(?P<seq>\\d{6})(?P<body>\\s+.*)$"

Column 7 is the INDICATOR AREA. It legitimately holds '*', '/', '-' or
```

'D'. On any such line the sequence number was never stripped, so a body
read as "001690/" was classified as executable COBOL and the terminator
pass punctuated it into "001690/." - not valid COBOL. The same defect
hid trailing IF ... WRITE ... END-IF blocks from the output-write pass.

Stripping is now COLUMN-BASED, with a regex fallback only for free-form
text that carries no fixed-format frame.

CORRECTION 2 - a duplicated sequence area survived

A line that had already been sequenced, then sequenced a SECOND time by
a later pass, reaches this module as:

    000380 000380* 2004/12 REPRENDRE N DE TITRE EN OUTPUT (12 POS 00380000
    ^^^^^^ ^   ^^^^^^^^
    cols1-6 col7   cols 73-80

Columns 1-6 are digits and column 7 is a blank indicator, so the line
passed is_fixed_format_line() and columns 8-72 were returned verbatim -
inner sequence and all. strip_sequence_numbers() now removes a nested
sequence area as well, capped and guarded so a legitimate body that
happens to begin with digits is never damaged.

CORRECTION 3 - the right sequence was removed without being verified
----
strip_right_sequence() truncated every fixed-format line at column 72.
A generated line whose body overran column 72 therefore lost real text
with no diagnostic. Columns 73-80 are now removed only when they are
actually an eight-digit sequence.

CORRECTION 4 - CRLF
----
rstrip("\\n") left a trailing '\\r' at position 80, displacing the right
sequence slice by one. Both line endings are removed.

CONTRACT (unchanged for callers)
----
strip_sequence_numbers(line) removes columns 1-6 and 73-80, KEEPING
column 7 onwards. A comment line therefore still begins with its '*' or
'/' indicator, which is what is_comment_or_blank() relies on.

logical_body(line) returns columns 8-72 only, indicator excluded.

This file contains regex patterns and pure text helpers only.
No business rules, no layout constants, no program names.

"""Regex for the structural safety passes. Regex only.

CORRECTION - numbered paragraphs were invisible
-----------------------------------------------
_NAME was [A-Z][A-Z0-9-]* , which requires a leading LETTER. Every
generated cursor paragraph is numbered:

    710-OPEN-DZBFASC1.
    720-FETCH-DZBFASC1.
    730-CLOSE-DZBFASC1.

None of them matched PARAGRAPH_HEADER_PATTERN, so the unreachable-code
guard was never disarmed and commented the whole generated block.

Two name classes are now declared. A DATA NAME must start with a letter.
A PARAGRAPH NAME may start with a digit.

# IDMS DB2 Phase 2 Converter
```

Standalone Phase 2 project for converting IDMS COBOL programs into DB2 embedded SQL COBOL.

Inputs

- Sheet Mapping Excel or CSV
- DCLGEN text file or multiple DCLGEN files
- Copybook text file
- Optional Copybook PDF
- IDMS COBOL source code

Output

- Converted DB2 COBOL code
- Validation messages
- Metadata overview
- Record summary
- Column summary
- Set / relationship summary
- Sheet Mapping preview

Clean Architecture Rule

Hardcoded names, aliases, regex patterns, and business rules must not live inside parsers or services.

Use:

- `catalogs/` for column names, aliases, SQL type lists, labels, and static catalog values
- `patterns/` for regex patterns
- `rules/` for business and conversion rules
- `converter/parsers/` for parsing logic only
- `converter/services/`, `generators/`, `resolvers/`, `transformers/`, and `validators/` for logic only

Run

From the project root:

```bash
set PYTHONPATH=.
python -m streamlit run converter/app.py --server.port 8502

$env:PYTHONPATH = "src"
python runners\run_update.py

python runners\convert_programs.py
python runners\run_update.py

python -m pip install "pytest>=9.1.1"
$env:PYTHONPATH = "."
python -m pytest tests -q

check

# Everything except the mainframe write
python -m mainframe.zowe_pipeline all --to review

# Resume after a failed convert, no re-download
python -m mainframe.zowe_pipeline all --from convert

# Convert and review only
python -m mainframe.zowe_pipeline all --from convert --to review

================================================================================================

"""CHK-14 End-of-cursor handling in the fetch paragraph.

CORRECTION - criterion 05 recognised only ONE of two valid loop shapes

    The converter drives a cursor with whichever idiom the source used,
    and CursorFlowComposer supports both:

        INLINE   PERFORM 720-FETCH-DZBFASC1 UNTIL DZBFASC1-EOC

        SPAN     PERFORM BEHANDELING THRU BEHANDELING-EXIT
                     UNTIL DZBFASC1-EOC

    Criterion 05 asserted the INLINE text verbatim with startswith(),
    so every span-loop program failed even though its cursor was
    correctly driven. The conversion log for VMDZ7200 says so plainly:

        Cursor flow: correlated cursor DZBFASC1 with span loop
        PERFORM BEHANDELING THRU BEHANDELING-EXIT.
        Cursor flow: rewrote span loop exit condition to DZBFASC1-EOC.
```

```
    It also required opener and terminator on ONE physical line, which a
    fixed-format program is free to split.

    The criterion now asserts the property that actually matters: SOME
    loop terminates on this cursor's end-of-cursor flag. Which paragraph
    the loop performs, and whether the statement spans lines, is a
    formatting choice - not a correctness property.

    Criteria 02 and 04 still carry the rest of the contract: the FETCH
    paragraph must SET the flag, and no loop may test raw SQLCODE.

"""CHK-18 SQL statements & host variable binding.

CORRECTION 1 - criterion 02 rejected every verb the converter emits
    The whitelist held only the four DML verbs:

        recognized = ("SELECT", "INSERT", "UPDATE", "DELETE")

    so every INCLUDE, DECLARE, OPEN, FETCH, CLOSE and COMMIT this
    converter deliberately generates was reported as an unrecognised
    SQL verb - 9 occurrences on a clean retrieval program. Embedded
    SQL has many more verbs than DML, and a cursor-driven conversion
    uses almost all of them.

CORRECTION 2 - criterion 01 depended on how blocks were parsed
    It asserted ``block.has("END-EXEC")`` on each parsed block, which
    makes the result a property of the BLOCK PARSER rather than of the
    program. Any parser weakness - for example a single-line
    ``EXEC SQL INCLUDE SQLCA END-EXEC.`` not being terminated on its
    own line - shows up as 6 "unclosed" blocks in a program where
    every block is, in fact, closed.

    The criterion now asserts the property the COMPILER cares about:
    the number of EXEC SQL openers equals the number of END-EXEC
    terminators. That holds whatever shape the parser produces.

CORRECTION 3 - criterion 03 was an unconditional PASS
    ``record.ok(...)`` was recorded without inspecting anything, which
    inflates the pass count and makes the report less trustworthy than
    an honest SKIP. It now reports SKIP with the reason, until the
    host-variable rule is implemented.

NOTE
    Both corrections were invisible until 10-10-2026, because this check
    raised AttributeError on every program and the reviewer downgraded
    it to BLOCK. A BLOCKED check does not fail a review, so CHK-18 had
    never actually inspected a single line of generated COBOL.

"""CHK-30 LRF subschema path expansion - WHERE clause generation.

Validates LRF (Logical Record Facility) path expansion per lrf_conversion_rules.py
and cursor_join_resolver.py:

1. OBTAIN <LR> WHERE <path-keyword> → OBTAIN FIRST <record> WITHIN <set>
2. Path keyword resolution from subschema (must be mapped)
3. Driving record required to be DB2-mapped (no UNKNOWN tables)
4. Extra filter conditions preserved for manual WHERE narrowing
5. Unmapped paths marked as KEEP for manual expansion
6. Set names correctly generated from path keyword
```

ENCODING: utf-8
================================================================================

"""Source-based program-kind detection for the review step.

The batch review path (zowe pipeline) runs over a folder of generated .cbl
files and passes a single, global ``--kind`` of UNKNOWN. A program's kind is a
per-program fact, not a per-run one, so every UPDATE program was reviewed as
UNKNOWN and its UPDATE-only checks (record modification, audit column / date
handling, restart structure) were silently skipped.

This detector recovers the kind from evidence that survives conversion:

* An explicit ``USAGE-MODE IS UPDATE|RETRIEVAL`` in the original source wins.
* An IDMS write verb (STORE / MODIFY / ERASE <record>) or a DB2 write statement
  (INSERT / UPDATE / DELETE issued through EXEC SQL) means the program changes
  data -> UPDATE. Write intent takes precedence, because a retrieval-only
  program never writes, whereas an update program routinely reads first.
* Otherwise an IDMS retrieval verb (OBTAIN / FIND) or a DB2 cursor / singleton
  read (DECLARE / FETCH / OPEN / SELECT) means -> RETRIEVAL.
* No evidence at all stays UNKNOWN.

The IDMS verb patterns require "VERB <record>", so paragraph names such as
210-STORE-EFF (STORE not followed by whitespace) never trigger a false match.
No program, record, table, column or host-variable name is hardcoded.

FILE: rules\cobol_standard_initialization_rules.py
ENCODING: utf-8
================================================================================

"""
COBOL Standard Initialization and Validation Rules (Issue #5).

Standards for applying COBOL best practices across all converted programs,
including counters, timestamps, and declarative validation sections.

This covers what the manual reference program includes that should be
standardized across all programs.

ISSUE #5 BREAKDOWN:
===================

5a) Processing Counters (D-2 in DEFERRED_DECISIONS)
    - Every program that processes records should have counters
    - Counters track rows read, rows written, errors
    - Counters are displayed at end-of-run (before STOP RUN)

    Status: AUTOMATE (approved by COBOL team)

    Counters declared:
        10  WS-NB-<TOKEN>-COUNT    PIC 9(7) COMP-3 VALUE ZEROES.

    where <TOKEN> is derived from:
    - Cursor/table name (middle part, distinctive)
    - "OUTPUT" for the output file counter

    Example:
        10  WS-NB-BEFF-COUNT       PIC 9(7) COMP-3 VALUE ZEROES.
        10  WS-NB-OUTPUT-COUNT     PIC 9(7) COMP-3 VALUE ZEROES.

5b) Timestamp Audit Fields
    - Programs should record start/end timestamps
    - Tracks when program executed and how long it ran
    - Stored in WORKING-STORAGE for end-of-run display

    Status: AUTOMATE (already in rules)
```

```
    Fields declared:
        01  WS-TIMESTAMPS.
            05  WS-EXEC-START-TIME   PIC 9(8) VALUE ZEROES.
            05  WS-EXEC-START-DATE   PIC 9(8) VALUE ZEROES.
            05  WS-EXEC-END-TIME     PIC 9(8) VALUE ZEROES.
            05  WS-EXEC-END-DATE     PIC 9(8) VALUE ZEROES.

5c) Program-Name Constant (D-4 in DEFERRED_DECISIONS)
    - Replace hardcoded MOVE 'VMDZ4420' TO PROGRAM-NAME
    - Use constant declared in WORKING-STORAGE

    Status: AUTOMATE (approved by COBOL team)

    Declared:
        10  CS-PROGRAM             PIC X(8)  VALUE 'VMDZ4420'.

    Used:
        MOVE CS-PROGRAM TO PROGRAM-NAME.

5d) DCLGEN Initialization (Issue #3)
    - Initialize all DCLGEN groups before processing
    - One-time initialization in dedicated paragraph (100-INITIALIZE)
    - NOT immediately after PROCEDURE DIVISION

    Status: ENFORCE (corrects placement issue)

    Declared:
        PROCEDURE DIVISION.
            PERFORM 100-INITIALIZE.
            PERFORM 200-OPEN-CURSORS.

        100-INITIALIZE.
            INITIALIZE DCLDZBEFFTV.
            INITIALIZE DCLDZEVEFTV.
            INITIALIZE DCLDZBEFF (if used).

5e) Counter Increment Logic
    - Every cursor FETCH loop should increment its counter
    - Output loop should increment output counter
    - Placement: immediately after successful operation

    Example:
        FETCH CURSOR-NAME
            MOVE DB2-FETCH-STATUS TO SQLCODE
            IF SQLCODE = 0
                ADD 1 TO WS-NB-BEFF-COUNT
                <-- Process record
            END-IF.

5f) End-of-Run Totals Display
    - Before STOP RUN, display all counters
    - Format: DISPLAY '<label> : ' <counter>
    - Labels should be descriptive and aligned

    Example:
        DISPLAY 'TOTAL BEFF RECORDS   : ' WS-NB-BEFF-COUNT
        DISPLAY 'TOTAL OUTPUT RECORDS : ' WS-NB-OUTPUT-COUNT
        STOP RUN.

5g) Validation Display (Optional)
    - Can include validation counts (errors, warnings, skipped)
    - Helps verify conversion correctness
    - Status: OPTIONAL (pending COBOL team review)

    Examples:
        DISPLAY 'VALIDATION: errors encountered'
        DISPLAY 'VALIDATION: records skipped (missing key)'
        DISPLAY 'VALIDATION: date conversions applied'

STANDARD COBOL CHECKLIST FOR CONVERTED PROGRAMS:
================================================
After conversion, every program should have:

WORKING-STORAGE additions:
- [ ] Program-name constant (CS-PROGRAM)
```

```
- [ ] Processing counters (WS-NB-<TOKEN>-COUNT) for each cursor
- [ ] Output file counter (WS-NB-OUTPUT-COUNT)
- [ ] Timestamp fields (WS-EXEC-START-TIME, etc.)
- [ ] DCLGEN initialization in dedicated paragraph (100-INITIALIZE)

PROCEDURE DIVISION structure:
- [ ] PERFORM 100-INITIALIZE before any processing
- [ ] Counter increment after each successful FETCH
- [ ] Counter increment after each successful output write
- [ ] End-of-run totals display before STOP RUN

VALIDATION:
- [ ] No hardcoded program names (use CS-PROGRAM)
- [ ] No hardcoded DCLGEN group names (use qualified OF references)
- [ ] All counters initialized to ZEROES
- [ ] All counters incremented correctly
- [ ] Timestamp fields populated (if used)
- [ ] DCLGEN groups initialized in 100-INITIALIZE paragraph

INTEGRATION WITH EXISTING RULES:
================================
This standard depends on and integrates with:
- counter_rules.py (counter declaration and display)
- timestamp_audit_rules.py (timestamp field generation)
- initialization_placement_rules.py (DCLGEN initialization timing)
- field_mapping_standards.py (no hardcoded field names)
- db2_date_conversion_standards.py (date field conversion)

DECISION MATRIX (for COBOL team):
==================================
Feature              | Automate? | Status   | Owner | Date
---------------------|-----------|----------|-------|----------
Processing Counters  | YES       | APPROVED | Team  | [Date]
Timestamps           | YES       | APPROVED | Team  | [Date]
Program Constant     | YES       | APPROVED | Team  | [Date]
DCLGEN Init Placement| YES       | ENFORCE  | Team  | [Date]
Counter Increment    | YES       | AUTOMATE | Team  | [Date]
End-of-run Display   | YES       | AUTOMATE | Team  | [Date]
Validation Display   | OPTIONAL  | REVIEW   | Team  | [Date]

# LOCATION: rules/cursor_close_guarantee_rules.py
# ACTION: CREATE NEW FILE

"""Cursor close-guarantee rules.

Constants only. No regex, no runtime logic, no program / paragraph /
record / table / cursor / host variable names.

WHY THIS EXISTS
---------------
`CursorFlowComposer` handles two loop idioms (INLINE and SPAN). When a
program matches neither - as every LRF-expanded program did - it logged
`no_loop_for_cursor` as a WARNING and emitted:

    PERFORM 710-OPEN-DZBFASC1.
    PERFORM 720-FETCH-DZBFASC1.        <- primes once, never loops
    ...
    PERFORM 720-FETCH-DZBFASC1.        <- orphan repeat fetch

with `730-CLOSE-DZBFASC1` declared but never performed. The cursor is
opened, read twice and leaked. This pass is the last-resort guarantee
that produces the manual reference shape:

    PERFORM 710-OPEN-DZBFASC1.
    PERFORM 720-FETCH-DZBFASC1 UNTIL DZBFASC1-EOC.
    PERFORM 730-CLOSE-DZBFASC1.

and drives the business paragraph from the FETCH paragraph:

    EVALUATE SQLCODE
      WHEN ZERO
           PERFORM BEHANDELING THRU BEHANDELING-EXIT

# LOCATION: rules/cursor_declaration_geometry.py
# ACTION: CREATE NEW FILE
"""Fixed-format geometry for a generated DECLARE CURSOR.

Constants only.

CORRECTION 9 - indents were hand-counted spaces.

Each indent was a space literal with its target column stated only in a
trailing comment, so the comment and the value could disagree and
nothing would notice. Every indent is DERIVED from its column number,
as rules/fixed_format_rules.py derives its widths from the column
boundaries. The rendered strings are byte-identical.

CORRECTION 18 - two indents, one column.

IND_CLAUSE and IND_SELECT_FIRST were computed separately from the SAME
COLUMN_CLAUSE. Identical today, one edit away from disagreeing. The
second is now DERIVED from the first, so the identity is stated rather
than coincidental.

DELIBERATE DUPLICATION - rules/db2_infrastructure_rules.py carries its
own IND_* for the LEGACY CursorDeclarationGenerator, whose output shape
genuinely differs. That file says in terms: do NOT unify them until the
legacy generator is deleted.
"""

FILE: rules\cursor_declaration_legacy.py
ENCODING: utf-8
================================================================================================

# LOCATION: rules/cursor_declaration_legacy.py
# ACTION: CREATE NEW FILE
"""Literals belonging ONLY to the legacy CursorDeclarationGenerator.

rules/db2_infrastructure_rules.py says of the duplicated indents:

    "When the legacy generator is deleted, delete its indents with it
     and these become the only copy. Until then, do NOT unify them -
     the output shapes genuinely differ."

This module is the other half of that instruction: the legacy-only
values live HERE, so deleting the legacy generator is one file plus one
import line, not an archaeology exercise.

CORRECTION 1 - three warnings were re-declared inside the generator.

MISSING_CURSOR_NAME, MISSING_TABLE_TEMPLATE and MISSING_COLUMNS_TEMPLATE
were module constants in cursor_declaration_generator.py while
rules/db2_infrastructure_rules.py and rules/cursor_declaration_warnings.py
already owned those names - and the wording had already drifted:

    legacy : "missing DB2 table mapping."
    rules  : "no DB2 table."

Two operators reading two reports of the same refusal saw two
sentences. The generator imports the catalogued text now; nothing is
declared here that another rules module already owns.

CORRECTION 2 - IND_CLAUSE[:-1] stood in for a column.

The WHERE keyword sits one column left of the other clause keywords.
That was expressed by slicing a character off another indent, which
breaks silently the moment COLUMN_CLAUSE moves. It is DERIVED from its
own column number now.
"""

"""Diagnostic catalogues for cursor declaration, join and ORDER BY.

ONE dictionary literal each. Post-hoc "MESSAGES[key] = ..." assignments
are what let a duplicate QUERYNO block hide in this module's ancestor.

KEY-SPACE CONTRACT
------------------
CursorOrderByResolver merges ORDER_BY_KEY_MESSAGES with
CURSOR_ORDER_BY_MESSAGES into one catalogue. The two key sets MUST stay
DISJOINT - a collision would silently shadow a diagnostic.
tests/test_rules_no_duplicate_constants.py asserts that.

CORRECTION 22 - two refusals had no message key.

cursor_declare/declare_refusal.py logs "missing_cursor_name" and
"missing_table". Neither existed, so _message() returned "" and both
refusals stayed SILENT - a cursor vanished from the program and the
conversion report did not say why. That is precisely the gap
CORRECTION 3 was supposed to close.

"""DB2 cursor DECLARE statement rules - single import point.
```

```
REFACTOR - one 330-line constants file became six subject modules:

    cursor_declaration_geometry.py    columns, indents, widths
    cursor_declaration_templates.py   clause text, QUERYNO
    cursor_declaration_where.py       WHERE policy, operand vocabulary
    cursor_declaration_order_by.py    ORDER BY policy and labels
    cursor_declaration_warnings.py    the DB2 WARNING blocks
    cursor_declaration_messages.py    the four diagnostic catalogues

Every existing `from rules.cursor_declaration_rules import X` keeps
working. New code may import the subject module directly.

This module DECLARES NOTHING of its own. A constant defined here would
be a seventh place to look, and the duplicate-assignment defect this
file has suffered twice starts exactly that way. The only statements
below are imports and one __all__.

NON_COLUMN_SENTINELS is owned by the record materialisation rules and
re-exported, never re-declared: a second copy diverges the day one of
them gains a new sentinel. It is named in __all__ so an import cleanup
cannot remove what the declare package imports from here.

rules/db2_infrastructure_rules.py re-exports the QUERYNO names FROM
here and assigns nothing. That direction must not reverse.

FILE: rules\cursor_declaration_templates.py
ENCODING: utf-8
================================================================================================

# LOCATION: rules/cursor_declaration_templates.py
# ACTION: CREATE NEW FILE
"""Clause text and QUERYNO for a generated DECLARE CURSOR.

    EXEC SQL DECLARE DZBFASC1 CURSOR WITH HOLD FOR
      SELECT CT_RKTGDSV_479BFAS
           , NR_ID_479BFAS
      FROM DZBFASTV
      ORDER BY NR_ID_479BFAS ASC
      FOR READ ONLY
             QUERYNO 254
    END-EXEC

CORRECTION 2 - QUERYNO did not match the manual reference.

The generated DECLARE carried QUERYNO 119 = 100 + (1 x 19) while manual
reference VMDZ7200 carries 254. DB2 EXPLAIN identifies a statement by
QUERYNO; a number the reference does not use cannot be tied back to the
documented access path.

Cursor order is 1-BASED and the renderer computes

    QUERYNO_BASE + (cursor_order x QUERYNO_STEP)

so QUERYNO_BASE is NOT the first value; it is the value at order 0. It
is DERIVED from the reference value, so changing QUERYNO_FIRST alone
moves every generated number and nothing else is touched.

CORRECTION 3 - the placeholder must stay {number}.

cursor_declare_builder renders with QUERYNO_TEMPLATE.format(number=...)
while rules/db2_infrastructure_rules.py used "{queryno}". Swapping the
two raises KeyError at render time. {number} is the live contract;
db2_infrastructure_rules re-exports from here and assigns nothing.

================================================================================================

# LOCATION: rules/cursor_declaration_warnings.py
# ACTION: CREATE NEW FILE
"""DB2 WARNING comment blocks emitted in place of a refused cursor.

EMITTED AS COBOL COMMENT LINES, so each line must fit
WARNING_BODY_WIDTH (65).

cobol_standards.FORBIDDEN_MARKERS contains "DB2 WARNING" deliberately:
a program that still carries one of these must FAIL production
validation rather than ship a cursor that cannot bind.

CORRECTION 7 - the warnings did not fit a COBOL line.

UNRESOLVED_JOIN_KEY_TEMPLATE rendered, with real names, to about 77
characters. The fixed-format composer therefore wrapped or truncated
the one line that explains why the cursor is missing. A diagnostic that
cannot be read is no diagnostic. The *_LINES tuples are sized for the
window.

CORRECTION 20 - WARNING_PREFIX was declared and then re-typed.

The prefix existed as a constant AND as a hardcoded "* DB2 WARNING: "
inside four templates - five copies of one literal, which is
CORRECTION 1's pattern in a file whose whole subject is avoiding it.
Every template is now BUILT from the prefix.

CORRECTION 21 - NO_TABLE_LABEL was missing entirely.
```

```
cursor_declare/declare_column_ownership.py imports it. Without it the
module raises ImportError on first import, so the whole declare package
fails to load.

"""WHERE qualification policy and the operand-parsing vocabulary.

CORRECTION 6 - one predicate shape carried two constant names.

CHILD_JOIN_PREDICATE_TEMPLATE and DRIVING_KEY_PREDICATE_TEMPLATE held
the SAME literal - one edit away from a silent divergence between the
relationship path and the driving-key fallback, two predicate shapes in
one WHERE clause for no stated reason. The fallback is DERIVED from the
join template. Separate NAMES because the call sites are separate
decisions; no longer separate VALUES.

CORRECTION 12 - SQL literals lived in the builder.

SYMBOL_OPERATORS, the qualifier separator, the host prefix and the
operand trim set were module constants inside
cursor_declare_builder.py. They are SQL facts rather than site policy,
but they are LITERALS and this is where literals live.

# LOCATION: rules/cursor_loop_rules.py
# ACTION: CREATE NEW FILE
"""Cursor driving-loop rules.

Constants only. No regex, no runtime logic, no program / paragraph /
record / table / cursor / host variable names.

WHY THIS EXISTS
---------------
rules/cursor_flow_rules.py describes ONE loop idiom:

    PERFORM 710-OPEN-<cursor>.
    PERFORM 720-FETCH-<cursor>.
    PERFORM <business>
        UNTIL SQLCODE = 100.

Older programs - and every LRF program, which predates that convention -
drive the loop with a paragraph span:

    PERFORM <business> THRU <business>-EXIT
        UNTIL LR-STATUS = 'VMBFAS-EOA'.

with the OPEN and the priming FETCH in a DIFFERENT paragraph, which may
appear BEFORE or AFTER the loop in source order.

Restructuring a span loop would rewrite working business flow, which the
business-flow rule forbids. The SPAN strategy is therefore deliberately
conservative: it fixes the exit condition and guarantees the cursor is
closed, and changes nothing else.
"""

"""Cursor ORDER BY cleanup rules.
```

```
Constants only. No regex, no runtime logic, no program / record / table /
cursor / host variable names.

WHY THIS EXISTS

CursorOrderCleanupComposer was written to remove ORDER BY clauses the
CONVERTER had invented - CursorOrderByResolver derives them from Sheet
Mapping primary keys, which is a guess. The composer could not tell a
guessed clause from a resolved one, so it removed both.

Manual reference VMDZ7200 (Train Case 3) orders its root cursor on
NR_ID_479BFAS ASC. The clause carries business meaning and must survive.

The correct place to stop a guess is at the point of the guess, not by
deleting rendered SQL afterwards. This pass is therefore OFF.

# LOCATION: rules/cursor_spec/cursor_spec_rules.py
# ACTION: CREATE NEW FILE
"""Cursor specification rules.

Constants only. No regex, no runtime logic, no program / record / table
/ cursor / host variable names.

CORRECTION 1 - parent and child were told apart by a PARAGRAPH NUMBER.

    return fetch_paragraph.split("-")[0][0] == "7"

cobol_standards.CURSOR_OPEN_NUMBERS is (710, 810, 910), so the THIRD
cursor in a program opens at 910 and the test returned False for it. A
program with three root sweeps mis-labelled two of them as children,
and cursor_paragraph_body_builder then emitted driving-key DISPLAY
lines for a cursor that has no driving key.

The discriminator is the DATA, not the numbering: a cursor with WHERE
predicates is driven BY something and is therefore a CHILD; a cursor
with none is a root/sweep and is the DRIVER. That is exactly the shape
the manual reference shows - 720-FETCH (no WHERE) reports the cursor
```

```
name only, 820-FETCH (four predicates) reports the four key values.

The series numbers are retained because they document the shop
convention and the review check reads them, but nothing classifies on
them any more.

CORRECTION 2 - CURSOR_OPERATIONS was declared twice.

The same frozenset lives in rules/program_flow_rules.py. One fact, two
modules: the day a fourth verb is added, one of them will be missed.
This module re-exports rather than re-declaring.

================================================================================================
FILE: rules\db2_date_conversion_standards.py
ENCODING: utf-8
================================================================================================

"""
Enhanced DB2 Date Conversion Standards (Issue #1).

Standards for DB2 DATE field conversion in COBOL, specifying:
- WHERE conversions must happen (before output, not inside loop)
- HOW to handle edge-case dates (01.01.0001, 31.12.9999)
- WHAT the conversion sequence must be

This file documents the STANDARD PATTERN that all date conversions must follow.
The rules folder contains the templates; this file documents the intent.

STANDARD SEQUENCE FOR DATE CONVERSION:
======================================

Step 1: Initialize helper fields (once at startup, NOT in loop)
    MOVE ZEROES TO DA-CCYYMMDD
    MOVE ZEROES TO <helper-field>

Step 2: Before processing any date field
    MOVE <source-date-from-dclgen> TO DA-DD-MM-CCYY

Step 3: Evaluate date value and convert
    EVALUATE TRUE
        WHEN DA-DD-MM-CCYY = '01.01.0001'
            MOVE ZEROES TO DA-CCYYMMDD-R
        WHEN DA-DD-MM-CCYY = '31.12.9999'
            MOVE '99999999' TO DA-CCYYMMDD-R
        WHEN OTHER
            MOVE CCYY OF DA-DD-MM-CCYY TO CCYY OF DA-CCYYMMDD-R
            MOVE MM   OF DA-DD-MM-CCYY TO MM   OF DA-CCYYMMDD-R
            MOVE DD   OF DA-DD-MM-CCYY TO DD   OF DA-CCYYMMDD-R
    END-EVALUATE

Step 4: Write converted date to output
    MOVE DA-CCYYMMDD-R TO <output-field>

CRITICAL REQUIREMENTS:
======================
1. Date initialization (ZEROES) happens ONCE before any processing
   - Location: dedicated INITIALIZE paragraph or WORKING-STORAGE VALUE clause
   - NOT inside fetch loop

2. Date comparison/conversion BEFORE write
   - Location: immediately before MOVE to output field
   - Reason: ensures output always receives converted value

3. Edge case handling is MANDATORY
   - '01.01.0001' (DB2 minimum) → '00000000' (COBOL zero date)
   - '31.12.9999' (DB2 maximum) → '99999999' (COBOL high date)
   - All other dates → CCYY-MM-DD realignment

4. No hardcoded field names in the conversion logic
```

```
   - DCLGEN group name: dynamic, from source metadata
   - Helper field name: derived from source field name
   - Output field name: from Sheet Mapping

5. Shared work fields reduce duplication
   - DA-CCYYMMDD (source structure for realignment)
   - DA-DD-MM-CCYY (helper for source input)
   - DA-CCYYMMDD-R (redefined numeric output)
   - Declared once in WORKING-STORAGE, reused for all dates

EXAMPLE (from VMDZ4420):
========================

WORKING-STORAGE SECTION.
    * DB2 DATE CONVERSION WORKING STORAGE
    01  WS-DATUMVELDEN.
        03  DA-CCYYMMDD.
            05  CC                    PIC 99       VALUE ZERO.
            05  YY                    PIC 99       VALUE ZERO.
            05  MM                    PIC 99       VALUE ZERO.
            05  DD                    PIC 99       VALUE ZERO.
        03  DA-CCYYMMDD-R REDEFINES DA-CCYYMMDD.
            05  CCYY                  PIC 9999.
            05  MM                    PIC 99.
            05  DD                    PIC 99.
        03  DA-DD-MM-CCYY.

            WHEN DA-DD-MM-CCYY = '01.01.0001'
                MOVE ZEROES            TO DA-CCYYMMDD-R
            WHEN DA-DD-MM-CCYY = '31.12.9999'
                MOVE '99999999'        TO DA-CCYYMMDD-R
            WHEN OTHER
                MOVE CCYY OF DA-DD-MM-CCYY TO CCYY OF DA-CCYYMMDD-R
                MOVE MM   OF DA-DD-MM-CCYY TO MM   OF DA-CCYYMMDD-R
                MOVE DD   OF DA-DD-MM-CCYY TO DD   OF DA-CCYYMMDD-R
        END-EVALUATE.
        MOVE DA-CCYYMMDD-R TO HELP-UIT-DA-UBSEC.
        <-- HELP-UIT-DA-UBSEC now contains converted date, ready for output

FIELD MAPPING INTEGRATION (Issue #2):
=====================================
All date conversions are driven by Sheet Mapping metadata:
- Source: DCLGEN field (e.g., DA-UBSECIS-479BEFF OF DCLDZBEFFTV)
- Target: Output record field (e.g., UIT-DA-UBSEC)
- Conversion: Automatically injected when source is DATE type

No hardcoding of DCLGEN names or field names occurs in the conversion logic.
Every source/target pair is looked up via Sheet Mapping.

VALIDATION CHECKLIST:
=====================
Before closing a conversion:
- [ ] All DATE fields in DCLGEN have conversion rules
- [ ] Conversion happens BEFORE output write, not inside loop
- [ ] Edge cases (01.01.0001, 31.12.9999) are explicitly handled
- [ ] Helper field is initialized once, not in loop
- [ ] No hardcoded field names in EVALUATE logic
- [ ] Sheet Mapping has SOURCE=DATE and valid TARGET field
- [ ] Output date fields are NUMERIC (PIC 9(8))
"""

"""DB2 INCLUDE emission rules.

Constants only. No regex, no runtime logic, no program / record / table
names.

WHY THIS EXISTS
---------------
Three components emitted EXEC SQL INCLUDE independently:

  InfrastructureBlockBuilder   3-line block, Area B
  DclgenIncludeCleanup         3-line block, 1 space
  StorageWsInjector            single line,  1 space

Two shapes and no shared duplicate detection. The update injector looked
for the SINGLE-LINE form, did not recognise the BLOCK form already
emitted upstream, and injected DZBFARTV a second time. A duplicated
DCLGEN include duplicates every data-name in the group, which the
compiler rejects.

Every emitter now renders through IncludeRenderer using these constants,
so the shape and the indent are decided in one place.

================================================================================================

"""
DB2 output date conversion rules.

This file contains reusable output-date conversion templates only.
No parser, service, transformer, composer, or generator logic belongs here.

Purpose:
- Convert DB2 date host fields into the output-file numeric date format
  before writing output records.
- Keep conversion rules centralized and generic.

No program name is hardcoded.
No table name is hardcoded.
No DCLGEN group name is hardcoded.
No business field name is hardcoded.

The composer supplies dynamic values:
- indent
- field_name
- group_name
- target_name

FILE: rules\field_mapping_standards.py
ENCODING: utf-8
================================================================================

"""
Field Mapping and MOVE Statement Standards (Issue #2).

Standards for how MOVE operations should work when converting from DCLGEN
fields to output record fields. This ensures field mappings are clean and
```

follow COBOL best practices.

STANDARD PATTERN FOR FIELD MAPPING:
==========

1. QUALIFIED REFERENCE (PREFERRED)
   Format: MOVE <field> OF <dclgen-group> TO <output-field>
   Example: MOVE AM-CNSTK-479BEFF OF DCLDZBEFFTV TO UIT-AM-CN-STOCK

   Rules:
   - DCLGEN field name comes from Sheet Mapping (SOURCE)
   - DCLGEN group name comes from DCLGEN metadata
   - Output field name comes from Sheet Mapping (TARGET)
   - Never invent or hardcode any of these

2. UNQUALIFIED REFERENCE (NOT RECOMMENDED)
   Example: MOVE AM-CNSTK-479BEFF TO UIT-AM-CN-STOCK

   Status: DEPRECATED
   Reason: No explicit DCLGEN group reference; loses traceability
   Use only when field name is globally unique (rare)

3. SPECIAL CASE: NUMERIC DATE FIELDS
   Pattern:
   - Convert date using DA-CCYYMMDD helper (see db2_date_conversion_standards.py)
   - THEN move converted helper to output field

   Example:
       MOVE DA-UBSECIS-479BEFF OF DCLDZBEFFTV TO DA-DD-MM-CCYY
       <-- (evaluate and convert)
       MOVE DA-CCYYMMDD-R TO UIT-DA-UBSEC

4. INITIALIZATION BEFORE MOVE (IF NEEDED)
   When output field may not have been cleared:

   INITIALIZE UIT-RECORD   <-- Once per paragraph or as needed
   MOVE <source> OF <group> TO <target>

VIOLATION PATTERNS TO AVOID:
==========

WRONG 1: Bare field reference (loses DCLGEN context)
    MOVE CCUSTK-479BEFF TO UIT-AM-CN-STOCK
    ^-- Which DCLGEN group? Unknown if field exists.

WRONG 2: Hardcoded DCLGEN or record names
    MOVE <field> OF DCLDZBEFFTV TO UIT-AM-CN-STOCK
    ^-- If DCLGEN name changes, hardcode breaks.

WRONG 3: Field name mismatch (Sheet Mapping error)
    MOVE AM-CNSTK-479BEFF OF DCLDZBEFFTV TO UIT-WRONG-FIELD
    ^-- Sheet Mapping says map to UIT-AM-CN-STOCK, not UIT-WRONG-FIELD

WRONG 4: Uninitialized output before move
    MOVE <field> TO UIT-RECORD
    <-- UIT-RECORD might have garbage from previous iteration

WRONG 5: Date without conversion
    MOVE DA-UBSECIS-479BEFF OF DCLDZBEFFTV TO UIT-DA-UBSEC
    ^-- DA field is DD.MM.CCYY; needs conversion to CCYYMMDD first

FIELD MAPPING CHECKLIST:
==========
For each MOVE statement to an output field:
- [ ] Source is DCLGEN field name (from Sheet Mapping SOURCE)
- [ ] DCLGEN group is explicitly stated (OF <group>)
- [ ] Target is Sheet Mapping TARGET field name
- [ ] If source is DATE type: conversion sequence done first
- [ ] If target needs clearing: INITIALIZE done before MOVE
- [ ] No hardcoded names in the MOVE statement
- [ ] If field has numeric picture, moving numeric source
- [ ] If field has alpha picture, moving alphanumeric source

```
INTEGRATION WITH SHEET MAPPING:
================================
The converter reads Sheet Mapping for:
- Column-to-DCLGEN mappings (SOURCE column)
- DCLGEN field-to-output mappings (TARGET field)
- Data type (SOURCE=DATE triggers conversion)

Example Sheet Mapping entry:
    | Sheet | Column | DCLGEN_Group | DCLGEN_Field | DCLGEN_Qual | OUTPUT_Field | Type |
    |-------|--------|--------------|--------------|-------------|--------------|------|
    | BEF   | AM_CNSTK | DCLDZBEFFTV | AM-CNSTK | 479BEFF | UIT-AM-CN-STOCK | CHAR |
    | BEF   | DA_UBSEC | DCLDZBEFFTV | DA-UBSECIS | 479BEFF | UIT-DA-UBSEC | DATE |

Converter generates:
    MOVE AM-CNSTK-479BEFF OF DCLDZBEFFTV TO UIT-AM-CN-STOCK
    <-- (for non-DATE fields)

    MOVE DA-UBSECIS-479BEFF OF DCLDZBEFFTV TO DA-DD-MM-CCYY
    <-- (date conversion sequence)
    MOVE DA-CCYYMMDD-R TO UIT-DA-UBSEC

IMPACT ON VALIDATION:
=====================
When validating output:
- All output fields should be populated via qualified MOVE statements
- Traceability: output field → Sheet Mapping TARGET → Sheet Mapping SOURCE → DCLGEN
- Date fields should have numeric conversion helper applied
- No uninitialized or partially initialized output records

TIMESTAMP FIELDS:
=================
Similar to DATE fields but for timestamp data.
- Source: TIMESTAMP-type DCLGEN field (format: YYYY-MM-DD-HH.MM.SS.NNNNNN)
- Conversion: Depends on OUTPUT field type (DATE vs full TIMESTAMP)
- Output: Target field format per Sheet Mapping
- Standard: Apply conversion before MOVE (like DATE fields)

ENCODING: utf-8
================================================================================================

"""
COBOL Initialization Placement Rules (Issue #3).

Standards for WHERE initialization statements are placed in the procedure,
ensuring they execute in the correct sequence per COBOL best practices.

STANDARD:
---------
1. INITIALIZE statements for DCLGEN groups (e.g., DCLDZBEFFTV) must be
   placed BEFORE the cursor is opened, not immediately after PROCEDURE DIVISION.

2. Placement sequence:
   PROCEDURE DIVISION.
       <-- INITIALIZATION PARAGRAPH (or inline)
       <-- DATE/TIME stamp section (if needed)
       <-- OPEN CURSOR
       <-- Main processing loop

3. If initializations are needed immediately before processing:
   - Place them in a dedicated paragraph like "100-INITIALIZE-DCLGEN"
   - Call this paragraph BEFORE opening cursors
   - This separates initialization logic from procedure flow
```

```
4. NEVER place initializations:
   - Immediately after PROCEDURE DIVISION.
   - Inside the cursor fetch loop (unless needed for that iteration)
   - After OPEN CURSOR

VIOLATION MARKERS:
- PROCEDURE DIVISION.
  INITIALIZE DCLGEN-GROUP.     <-- WRONG (immediate)
  OPEN CURSOR-NAME.             <-- Cursor open follows directly

CORRECT PATTERN:
- PROCEDURE DIVISION.
  PERFORM 100-INITIALIZE-DCLGEN.
  PERFORM 200-OPEN-CURSORS.
  <-- Main flow

RATIONALE:
- DCLGEN initialization must happen once at startup, not per fetch
- Separating concerns keeps code maintainable
- Follows COBOL section/paragraph flow conventions
- Mirrors manual reference program structure

"""LRF -> classic IDMS expansion rules.

Constants only. No regex, no runtime logic, no program / record / table /
set / cursor / host variable names.

WHY THIS EXISTS

The converter already knows how to turn

    OBTAIN FIRST <record> WITHIN <set>.

into a DB2 cursor with OPEN / FETCH / CLOSE paragraphs, join predicates,
QUERYNO and an EOC flag.

It does NOT know the Logical Record Facility form

    OBTAIN FIRST <logical-record> WHERE <path-keyword>.

Teaching every downstream generator about logical records would duplicate
that machinery. Instead, a single pre-pass rewrites the LRF form into the
classic form using the parsed subschema path, and every existing rule
applies unchanged.

"""Mapping validation scope rules.

Constants only. No regex, no runtime logic, no program / record / table
names.

WHY THIS EXISTS
---------------
MappingValidator walks the ENTIRE Sheet Mapping workbook and reports any
table carrying rows but no usable DB2 columns. That is correct for a
workbook audit and wrong for a per-program conversion report: a retrieval
program is marked with two blocking errors for restart tables it never
touches.

A mapping gap is only an ERROR for a table the program being converted
actually references. For every other table it is an informational note
about the workbook, and it belongs in the conversion log.

# LOCATION: rules/structural_safety_rules.py
# ACTION: REPLACE ENTIRE FILE
"""Structural safety rules for generated COBOL.

Constants only. No regex, no runtime logic, no program / paragraph /
record / table / cursor / host variable names.

WHY THIS EXISTS
---------------
Three passes move or insert lines: the output-write extraction, the
counter declaration and the layout composer. Each was written against one
program shape. On an older program they produced source the compiler
rejects:

  A1. an IF whose CONDITION spans lines was split across two paragraphs,
  A2. a whole-record MOVE survived after the record's copybook was
      removed, leaving an undefined data-name,
  A4. a duplicate statement was left after a paragraph EXIT, unreachable
      and outside any paragraph,
  A5. a counter was declared INSIDE the 01 output record, shifting every
      byte of a fixed-length record.

Every rule here makes a pass REFUSE rather than guess. Refusing leaves
working COBOL and a diagnostic; guessing produces source that will not
compile.
"""

from __future__ import annotations

# ================================================================

================================================================================

"""
Timestamp Conversion Standards and Generic Paragraph (Change 2).

Standards for timestamp handling across all converted programs. Defines
the generic 600-GET-TIMESTAMP paragraph that captures system time/date
and converts it to TS-TIMESTAMP format for standardized use.

This implements a REUSABLE, GENERIC timestamp paragraph that every program
can call, eliminating duplication.

STANDARD TIMESTAMP STRUCTURE:
============================

Working-storage section includes TWO timestamp groups:

1. TS-SYSTEM: Raw output from FUNCTION CURRENT-DATE (21 bytes)
   Format: CCYYMMDDHHMMSSNNNNNN (where NN = 100ths of second)

   01  WS-TIMESTAMP-FIELDS.
       05  TS-SYSTEM.
           10  DA-SYS.
               15  DA-SYS-CCYY.
                   20  CC                  PIC X(2).
                   20  YY                  PIC X(2).
               15  MM                      PIC X(2).
               15  DD                      PIC X(2).
           10  HR-SYS.
               15  HH                      PIC X(2).
               15  MI                      PIC X(2).
               15  SS                      PIC X(2).
               15  TT                      PIC X(2).

2. TS-TIMESTAMP: Formatted human-readable timestamp (26 bytes)
   Format: CCYY-MM-DD-HH.MI.SS.TT

       05  TS-TIMESTAMP.
           10  CC                          PIC X(2).
           10  YY                          PIC X(2).
           10  TE-MARKER1                  PIC X     VALUE '-'.
           10  MM                          PIC X(2).
           10  TE-MARKER2                  PIC X     VALUE '-'.
           10  DD                          PIC X(2).
           10  TE-MARKER3                  PIC X     VALUE '-'.
           10  HH                          PIC X(2).
           10  TE-MARKER4                  PIC X     VALUE '.'.
           10  MI                          PIC X(2).
           10  TE-MARKER5                  PIC X     VALUE '.'.
           10  SS                          PIC X(2).
           10  TE-MARKER6                  PIC X     VALUE '.'.
           10  TT                          PIC X(2).
           10  NNNN                        PIC 9(04) VALUE 0.

GENERIC PARAGRAPH: 600-GET-TIMESTAMP
====================================

Every converted program includes this paragraph to capture and format
the current date/time. Call it whenever you need current timestamp.

600-GET-TIMESTAMP.
    MOVE FUNCTION CURRENT-DATE TO TS-SYSTEM.
    MOVE CC OF TS-SYSTEM TO CC OF TS-TIMESTAMP.
    MOVE YY OF TS-SYSTEM TO YY OF TS-TIMESTAMP.
    MOVE MM OF TS-SYSTEM TO MM OF TS-TIMESTAMP.
    MOVE DD OF TS-SYSTEM TO DD OF TS-TIMESTAMP.
    MOVE HH OF TS-SYSTEM TO HH OF TS-TIMESTAMP.
    MOVE MI OF TS-SYSTEM TO MI OF TS-TIMESTAMP.
    MOVE SS OF TS-SYSTEM TO SS OF TS-TIMESTAMP.
    MOVE TT OF TS-SYSTEM TO TT OF TS-TIMESTAMP.

USAGE EXAMPLE:
==============
```

```
PROCEDURE DIVISION.
    PERFORM 100-INITIALIZE.
    PERFORM 600-GET-TIMESTAMP.          <- Capture start timestamp
    DISPLAY 'Program started at: ' TS-TIMESTAMP.
    PERFORM 200-OPEN-CURSORS.
    PERFORM 300-MAIN-PROCESSING.
    PERFORM 400-CLOSE-CURSORS.
    PERFORM 600-GET-TIMESTAMP.          <- Capture end timestamp
    DISPLAY 'Program ended at: ' TS-TIMESTAMP.
    STOP RUN.

BENEFITS:
=========
1. GENERIC: Same paragraph works for any program (no customization needed)
2. REUSABLE: Call 600-GET-TIMESTAMP as many times as needed
3. STANDARD: Same format across all programs (CCYY-MM-DD-HH.MI.SS.TT)
4. SIMPLE: Just one PERFORM call to get formatted timestamp
5. NO DUPLICATION: Paragraph is declared once, used everywhere

TIMESTAMP LOCATIONS (Standard Placements):
==========================================
Call 600-GET-TIMESTAMP at:
1. Program startup (before PERFORM 200-OPEN-CURSORS)
2. Before main processing loop
3. After main processing loop completes
4. Just before STOP RUN

Each call updates TS-TIMESTAMP with current system time. Store in
WS-EXEC-* fields if you need to preserve timestamps across calls.

INTEGRATION WITH ISSUE #5:
==========================
WS-EXEC-START-TIME and WS-EXEC-END-TIME (separate numeric fields)
store the time portion for calculation purposes.

When you need to CAPTURE a timestamp for storage:
    PERFORM 600-GET-TIMESTAMP
    MOVE TS-TIMESTAMP TO WS-AUDIT-TIMESTAMP
    OR
    MOVE SS OF TS-TIMESTAMP TO WS-EXEC-START-TIME

When you need to DISPLAY current time:
    PERFORM 600-GET-TIMESTAMP
    DISPLAY 'Current: ' TS-TIMESTAMP

VALIDATION CHECKLIST:
====================
[ ] TS-SYSTEM group structure in WORKING-STORAGE (raw CURRENT-DATE)
[ ] TS-TIMESTAMP group structure in WORKING-STORAGE (formatted)
[ ] 600-GET-TIMESTAMP paragraph exists in PROCEDURE DIVISION
[ ] Paragraph moves from TS-SYSTEM to TS-TIMESTAMP correctly
[ ] All 9 field moves are present (CC, YY, MM, DD, HH, MI, SS, TT)
[ ] 600-GET-TIMESTAMP called at startup
[ ] 600-GET-TIMESTAMP called before major operations
[ ] TS-TIMESTAMP used in DISPLAY statements
[ ] Format is always CCYY-MM-DD-HH.MI.SS.TT
"""

from __future__ import annotations

# Update standard generator COBOL templates and literals.
#
# This module owns ALL generated COBOL layout text so the generator holds
# no COBOL literals. Only dynamic values (record, field, table, host names)
# are substituted at fill time. No program/record/table names are hardcoded;
# those arrive as .format() kwargs from resolved metadata.
#
# Layout rules enforced here:
# - Area A starts at column 8, Area B at column 12. A template line's leading
#   spaces are relative to column 8, so a level-02 item needs 4 spaces.
# - Every EXEC SQL block is preceded by a MOVE to SQL-LOCATION, so a failure
#   reports the paragraph that actually failed (CHK-20.07).
# - No period terminates a statement inside EVALUATE. Only END-EVALUATE
#   carries one (cobol_standards.ENFORCE_NO_PERIOD_IN_EVALUATE).

"""Validation and diagnostics presentation rules.

Constants only. No regex, no runtime logic, no program / record / table
names.

WHY THIS EXISTS
---------------
`validation_messages` is a single flat list that every generator and
composer appends to. It mixes three very different things:

  1. INPUT and MAPPING failures    - the run produced unusable output
  2. SKIPS and GAPS                - the run needs a human decision
  3. PASS NARRATION                - a composer reporting normal work

The Validation tab rendered all three through st.warning(), so eighty
lines of "a pass did its job" drowned the two lines that mattered.

Classification is PREFIX-FIRST and keyword-second, so a new composer that
follows the existing "Prefix: text" convention is categorised correctly
without touching this file.

================================================================================================
FILE: runners\line_preservation_audit.py
ENCODING: utf-8
================================================================================================

# LOCATION: runners/line_preservation_audit.py
# ACTION: REPLACE ENTIRE FILE

"""
Line-preservation audit tool.

Answers the core question:
    "Did the converter change ONLY the IDMS/DB2 lines and leave every other
     business line byte-for-byte identical?"

This is the CORRECT benchmark for a surgical IDMS->DB2 converter — NOT a
match against a human rewrite manual (which adds paragraph renaming,
counters, restructuring, etc. that the converter deliberately does not do).

Classification of each INPUT line:
    CONVERTIBLE  -> allowed to change (IDMS statement / control / mapped ref)
    PRESERVE     -> must appear unchanged in the output
    COMMENT/BLANK -> ignored

The audit reports:
    - PRESERVE lines that were dropped or modified   -> POTENTIAL BUG
    - CONVERTIBLE lines that changed                 -> expected
    - A pass/fail summary

Usage (from project root, with PYTHONPATH=src):
    python src\\converter\\testing\\line_preservation_audit.py ^
        --input  C:\\S\\S-Input\\Update.txt ^
        --output C:\\S\\S-Input\\Output\\Update_<timestamp>.cbl ^
        [--verbose]

"""Runs the project's pytest suite and returns structured results.

Design notes
------------
- pytest is invoked as a SUBPROCESS, never imported in-process. A test
  module that mutates global state, monkeypatches a shared service or
  calls sys.exit would otherwise corrupt the running Streamlit session.

- Results are read from pytest's JUnit XML report. That format is part
  of pytest core, so no plugin is added to the project's dependencies,
  and parsing is deterministic rather than scraping console text.

- PYTHONPATH is set explicitly for the child process. The converter
  lives under src/ while rules/, patterns/ and catalogs/ sit at the
  project root, so both entries are required.

- The run is bounded by a timeout. A hanging suite must not hang the UI.

This module contains no Streamlit code and no COBOL knowledge.

"""Converts one retrieval program and prints its report.

CORRECTION - LRF metadata was never supplied
--------------------------------------------
`ConversionInput` carries a `logical_records` field. This runner never
populated it, so `LrfRepository` was always empty, `LrfPathExpander`
returned the source unchanged, and every program using COPY IDMS LR
shipped with raw LRF syntax:

    OBTAIN FIRST VMBTL03-R01 WHERE SWEEP-VMBFAS.

No expansion means no `OBTAIN ... WITHIN ...`, which means no cursor,
no OPEN/FETCH/CLOSE paragraphs and no SQLERROR anchor. The failure was
silent because LRF is optional by design.

The records are now loaded from the configured LRF folder when the
caller does not supply them, so run_retrieval.py needs no change.

READING
-------
The subschema is read with utf-8-sig, which transparently strips a UTF-8
byte order mark. A BOM left in the file makes the first token of
`ADD SUBSCHEMA ...` unmatchable and yields zero logical records with no
error at all.
"""

# LOCATION: tests/conftest.py
# ACTION: CREATE NEW FILE

"""Shared pytest configuration and fixtures.

WHY THIS FILE EXISTS
--------------------
1. sys.path bootstrap.
   The converter lives under src/ while rules/, patterns/ and catalogs/
   sit at the project root, so BOTH must be importable. README documents
   $env:PYTHONPATH = "." but a forgotten environment variable then
   reports as a mysterious collection error. Setting it here makes
   `python -m pytest tests -q` work from a clean shell.

2. One shared transformer context.
   build_transformer_context() used to live inside a test module, and
   other test modules imported it with

       from tests.test_idms_statement_transformer import build_transformer_context

   Importing one test module from another depends on rootdir, on pytest's
   import mode and on collection order, and it breaks the moment the file
   is renamed. conftest.py is auto-discovered, so nothing imports anything.

Use either form:

    def test_x(transformer_context):            # fixture
        ...

    def test_y():                               # plain call
        context = build_transformer_context()
"""

    CORRECTION - a refusal was asserted by LINE COUNT.

        assert len(bodies) == 1

    pinned the single-line warning. That form rendered to ~77
    characters with real names, and the COBOL body window is columns
    8-72 - sixty-five - so the fixed-format composer wrapped or
    truncated the one comment explaining why a cursor is missing. The
    block is MULTI-LINE now, and a count was never the property worth
    asserting.

    What matters:
      - something is emitted, so the gap is visible in the source
      - every line carries the marker, so production validation and
        CHK-02 FORBIDDEN_MARKERS both catch it
      - every line fits the window, so nothing is truncated
      - no SQL is rendered, so nothing un-bindable reaches the program

"""Every way the declare builder REFUSES, and how it reports it.

    D-6  empty column list rendered SELECT *    -> CHK-12.04 reject
    D-7  WHERE ownership guard was dropped      -> SQLCODE -206
    D-10 spec-level refusals were SILENT        -> cursor vanished

GOVERNING RULE
--------------
The converter may REFUSE to generate SQL it cannot resolve. It must
never GUESS, and it must never refuse in silence. A refusal has two
halves and both are asserted here:

    the COBOL   a DB2 WARNING block, sized for the body window
    the report  a message on builder.messages naming the reason

cobol_standards.FORBIDDEN_MARKERS contains "DB2 WARNING" deliberately,
so a program still carrying one FAILS production validation rather than
shipping a cursor that cannot bind.

# LOCATION: tests/test_condition_scanner_measures_multiline.py
# ACTION: REPLACE ENTIRE FILE
"""Condition measurement, and the scope at which it is allowed to decide.

REGRESSION 1 - a dangling boolean operator closed a condition
-------------------------------------------------------------
condition_end_index() inspected only the NEXT line's first word, so

    IF (HELP-DA-CPTAFS-479BFAS < DA-ARCH-YMD  AND
    HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR
    (HELP-DA-CRFMAS-479BFAS < DA-ARCH-YMD AND
    HELP-DA-CPTAFS-479BFAS = '00000000')

measured as ONE line. OutputWriteGuard then allowed an extraction that
cut the IF away from its own condition tail:

    IF (HELP-DA-CPTAFS-479BFAS < DA-ARCH-YMD  AND
       PERFORM WRITE-FORM-REC
    END-IF.
    ...
    WRITE-FORM-REC.
       HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR

REGRESSION 2 - the guard decided PROGRAM-WIDE
---------------------------------------------
The fix for regression 1 over-corrected. blocks_extraction() refused
every extraction in a program when ANY PROCEDURE DIVISION IF carried a
multi-line condition. VMDZ4420 carried three two-line business status
tests in the same paragraph as its write block; the write block's own
guard, IF WS-STATUS = 'C', is one line and safe to cut. Three of six
programs lost WRITE-<record> and WS-NB-OUTPUT-COUNT.

The decision is now blocks_candidate(), scoped to one candidate.
blocks_extraction() survives as MEASUREMENT only - the tests below name
it that way so the distinction cannot be lost again.

================================================================================================

# LOCATION: tests/test_cursor_generation_contract.py
# ACTION: CREATE NEW FILE

"""Contract tests for the generated cursor block.

Each test pins one defect that reached a production-shaped output and was
fixed. They are unit tests on the builders - no Sheet Mapping, no DCLGEN,
no file I/O - so they run in milliseconds and fail for exactly one reason.

REGRESSION 1 - stale host data after a non-zero SQLCODE
-------------------------------------------------------
DB2 leaves the host variables UNCHANGED when a FETCH returns SQLCODE 100
or a negative code. Without INITIALIZE the DCLGEN group still holds the
PREVIOUS row and every downstream MOVE ... OF <group> copies stale values
into the output record.

REGRESSION 2 - SQLERROR reported a stale location
-------------------------------------------------
SQLERROR displays SQL-LOCATION. Setting it only at paragraph entry lets
any statement in between leave a stale value, sending the operator to the
wrong paragraph.

REGRESSION 3 - no QUERYNO on the DECLARE
----------------------------------------
DB2 EXPLAIN identifies a statement by QUERYNO. Without one, an access
path cannot be tied back to the cursor that produced it.

"""ORDER BY must survive on every cursor.

REGRESSION - a resolved ORDER BY was deleted

CursorDeclareBuilder dropped ORDER BY from any cursor with no WHERE, and
CursorOrderCleanupComposer stripped it again from the rendered text. Two
independent strippers for one clause.

Manual reference VMDZ7200 (Train Case 3) ends its ROOT cursor with

    ORDER BY NR_ID_479BFAS ASC
    FOR READ ONLY
    QUERYNO 254

Row sequence is business meaning: the extract file inherits it.

NOTE - CursorDeclareBuilder.build() takes a CursorSpec, never a dict.
Db2InfrastructureGenerator builds plain dicts and CursorSpec.read()
normalises them, so the fixture below goes through the same door the
production path uses.

# ACTION: REPLACE ENTIRE FILE
"""SELECT / INTO parity and full-record coverage.

REGRESSION 1 - the FETCH did not read what the program consumed

The generated FETCH carried 10 host variables:

    INTO :DCLDZBFASTV.DA-CPTAFS-479BFAS
       , :DCLDZBFASTV.DA-CRFMAS-479BFAS
       ... 8 more

while the business paragraph moved 83 fields out of the same group:

    *DB2: Materialised VMBFAS from DCLDZBFASTV - 83 field move(s).

73 fields were cleared by INITIALIZE and never fetched, so the output
record carried zeroes and spaces for most of its length.

REGRESSION 2 - two carriers, one sequence

SELECT and INTO are POSITIONAL and are rendered by two different
builders from two different carriers of the same spec dict:

    spec["select_columns"] -> CursorSpec -> CursorDeclareBuilder -> SELECT
    spec["host_variables"]              -> CursorParagraphBody   -> INTO

CursorSpec re-normalises and de-duplicates select_columns; the host
list is resolved separately and is NOT re-normalised. Any divergence
between the two is silent and corrupts every fetched row, so the
invariant is asserted here rather than trusted.

def test_empty_usage_on_a_non_materialised_record_selects_nothing():
    """No proven usage and not materialised -> no columns from THIS layer.
```

```
    CORRECTION - this test asserted a fallback the resolver no longer
    performs, and had been failing since that change.

    DESIGN (verified 10-10-2026 across all six sample programs):
    a non-materialised record with no proven usage returns an EMPTY list
    here. Columns arrive later from exactly two places:

      * force_full_record=True, for a record the materialisation composer
        copies as a whole - see the test below, and
      * the cursor_spec_builder augmentation pass, which adds the parent
        key columns a child cursor's WHERE clause needs.

    Falling back to the full mapped record here would over-select: the
    manual reference programs name a specific column list, and
    cobol_standards.ENFORCE_CURSOR_EXPLICIT_COLUMNS forbids a blanket
    projection.

    EVIDENCE the path is unreachable in practice: the conversion log
    emits 'no_usage_no_full_record' zero times for the sample set, and no
    generated program contains a SELECT with an empty column list.
    """

"""Cursor WHERE resolution and declaration contract.

Nine defects are pinned here, one group each. Every group names the
defect it prevents, so a failure tells the reader WHAT regressed, not
only which assert broke.

    D-1  fallback constants were never imported      -> NameError
    D-2  host_for_column() is not a resolver method  -> AttributeError
    D-3  fallback built a self-referential predicate -> meaningless filter
    D-4  only resolve() was tolerated on the facade  -> AttributeError
    D-5  condition.child_table read without getattr  -> AttributeError
    D-6  empty column list rendered SELECT *         -> CHK-12.04 reject
    D-7  WHERE ownership guard was dropped           -> SQLCODE -206
    D-8  parent/child ORDER BY rule was dropped      -> manual divergence
    D-9  a WHERE-less cursor was emitted silently    -> undetectable gap

No real customer name is asserted against; the fixtures define their own.

CORRECTION 1 - a refusal was asserted by LINE COUNT.

    assert len(bodies) == 1
```

```
pinned the single-line DB2 WARNING. That form rendered to ~77
characters with real names, and the COBOL body window is columns 8-72 -
sixty-five - so the fixed-format composer wrapped or truncated the one
comment that explains why a cursor is missing. The warning is a
MULTI-LINE block now, and a line count was never the property worth
asserting. _assert_refusal() checks what matters: every line carries
the marker, every line fits the window, and no SQL is emitted.

CORRECTION 2 - a test could not fail.

    assert resolver.where_conditions(CHILD_RECORD) == [] or True

`or True` makes the assertion unconditional. It caught only an
exception, which is what D-1 is about, so it now says that instead of
pretending to check a value.

CORRECTION 3 - the parent ORDER BY test was declared twice.

test_a_parent_cursor_also_keeps_order_by and
test_a_parent_cursor_keeps_order_by were the same test under two names.
Both ran, both passed, and a reader had to diff them to learn that.

# LOCATION: tests/test_db2_date_comparison.py
# ACTION: CREATE NEW FILE

"""DB2 DATE comparison conversion.

REGRESSION CONTRACT
-------------------
A DB2 DATE host is stored as DD.MM.CCYY (10 bytes). A COBOL date field is
CCYYMMDD, PIC 9(8). Comparing them directly compares '0' against '2' and
selects the wrong rows. Every DATE host that takes part in a comparison
must therefore be realigned into its HELP- helper first.

The two historical blockers, each fatal on its own:

  1. the host had to be the FIRST token after IF, so a parenthesised
     condition never matched,
  2. the condition had to contain the literal token PARMDATE, a hardcoded
     host variable belonging to one program.
"""

================================================================================================

"""Test that FFRECAB (restart table) is filtered from DCLGEN dependency resolution.

Background:
  VM1BD526 and VM1BD567 perform OBTAIN on FFRECAB (a control record for restart
  state management). The resolver was blindly generating DZECABTV as a DCLGEN
  dependency for this record. However:

  1. FFRECAB is not a data table; it's a restart control structure
  2. The converted programs use DZ01RSTV (standard restart table infrastructure)
  3. DZECABTV was never found in the fetch phase (warning spam)
  4. Manual team outputs never reference DZECABTV (it's unnecessary)

Solution:
  Filter FFRECAB from the _NOT_A_RECORD set so it never generates a DCLGEN.
  This matches the manual team behavior and eliminates wasteful fetch attempts.

Testing:
  Verify that OBTAIN FFRECAB does NOT produce DZECABTV in the DCLGEN list.

================================================================================================

# LOCATION: tests/test_marker_banner_width.py
# ACTION: REPLACE ENTIRE FILE
"""Generated marker banners must fit the fixed-format body window.

REGRESSION

DB2_INFRASTRUCTURE_MARKER is 69 characters. The banner template pads
with {title:<62} but never truncates, so the rendered banner ran past
column 72 and the fixed-format writer wrapped it:

    002350*DB2 SQLCA, SQL ERROR WORKING STORAGE, DCLGEN INCLUDES, AND CURSOR
    002360*FLAGS*

The phrase was split and the second line carried no opening asterisk.

TEST ISOLATION

The banner template is declared locally rather than imported. What is
under test is the TITLE SELECTION made by InfrastructureBlockBuilder,
not the renderer that formats it. Importing the real template would
couple this test to a constant owned by another module and would break
collection if that module is reorganised - which is exactly what
happened on the first two attempts at this file.

================================================================================================

# LOCATION: tests/test_no_pass_loses_characters.py
# ACTION: CREATE NEW FILE
"""No pass may lose characters from a PROCEDURE DIVISION statement.

REGRESSION
----------
A four-line IF condition reaches the generated file as two lines cut
mid-name:

    IF (HELP-DA-CPTAFS-479BFAS < DA-ARCH-YMD  AND HELP-DA-CPTAFS-
       (HELP-DA-CRFMAS-479BFAS < DA-ARCH-YMD AND HELP-DA-CPTAFS-4

losing "NOT = '00000000') OR" and "= '00000000')" entirely.

WHY THIS FILE EXISTS ALONGSIDE test_condition_is_never_truncated.py
-------------------------------------------------------------------
That file asserts the same property against ProcedureIndentNormalizer
ONLY, and passes. Pipeline instrumentation then proved the normalizer is
a no-op on the real program: debug_indent_in.txt and debug_indent_out.txt
are byte-identical, and the condition arrives ALREADY merged.

So the damage is done by a pass that no test covers. This file applies
the same assertion to every candidate, so the failing one names itself.

```

```
# ACTION: REPLACE ENTIRE FILE
"""The COMMIT removal must never empty a paragraph.

The replacement is a COMMENT, which is not executable. A paragraph whose
only statement was the COMMIT block would be left with nothing the
compiler accepts.

FIXED-FORMAT NOTE - the helper below builds a FULL 80-column record:

    columns  1-6   left sequence
    column   7     indicator
    columns  8-72  body (65)
    columns 73-80  right sequence

A short line is not merely cosmetic here: strip_sequence_numbers() stops
recognising the right sequence, the trailing digits stay glued to the
logical line, and a paragraph header reads as a statement.

================================================================================
FILE: tools\downstream_probe.py
ENCODING: utf-8
================================================================================

# LOCATION: tools/downstream_probe.py
# ACTION: CREATE NEW FILE

"""Finds which post-conversion pass corrupts a rewritten IF condition.

BACKGROUND
----------
tools/date_rewrite_probe.py proved Db2DateComparisonRewriter emits four
clean 80-column records:

        IF (HELP-DA-CPTAFS-479BFAS < DA-ARCH-YMD
           AND HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR
           (HELP-DA-CRFMAS-479BFAS < DA-ARCH-YMD AND
           HELP-DA-CPTAFS-479BFAS = '00000000')

The generated file contains six records with a stray '0' on three of
them:

        AND 0
        HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR 0
        = '00000000') 0

A bare '0' is the first character of the right sequence area 02610000,
so some pass is reading the body as columns 8-73 instead of 8-72, or is
re-wrapping a body that already carries sequence digits.
```

```
This probe feeds the KNOWN-GOOD records to each candidate pass in turn
and reports the first one that changes the line count or introduces a
stray token.

    $env:PYTHONPATH = "."
    python tools\downstream_probe.py

"""Developer probe: verify every `from rules.X import (...)` name exists.

Scans the project for imports from rules/, patterns/ and catalogs/, then
checks that each imported name actually exists in the target module.

Catches the exact failure class that has cost this project several
round-trips: a constant referenced by a composer or generator but never
declared in its rules file, which only surfaces at runtime as

    ImportError: cannot import name 'COMMENT_BLOCK_TEMPLATE' from
    'rules.cursor_paragraph_rules'

BOM HANDLING
------------
Several source files in this project are saved as UTF-8 WITH a byte order
mark. Python imports them without complaint because the import machinery
uses utf-8-sig, but ast.parse() on text read as plain utf-8 fails with

    invalid non-printable character U+FEFF

That is a reader defect, not a source defect, so this probe reads with
utf-8-sig and reports a BOM separately as a hygiene note.

Run from the project root:

    $env:PYTHONPATH = "."
    python tools\\rules_probe.py

Exit codes: 0 all names resolve, 1 one or more are missing.
"""
