"""Generic flow analyzer for diagnostics.

This analyzer does not rewrite COBOL. It detects:

    - procedure paragraphs
    - cursor-like operations from parsed IDMS operations
    - output write statements, separated from IDMS update verbs
    - date / timestamp usage hints

REFACTOR - one 330-line class became six collaborators:

    flow_line_reader.py            raw records -> classified lines
    flow_paragraph_scanner.py      paragraph spans, line ownership
    flow_cursor_loop_scanner.py    IDMS operations -> CursorLoop
    flow_write_scanner.py          WRITE vs IDMS update verbs
    flow_date_scanner.py           date / timestamp tokens
    flow_diagnostics.py            the report

The public surface is UNCHANGED: analyze() still returns one
ProgramFlowAnalysis and ProgramFlowAnalyzer keeps its constructor.

"""Derives one CursorLoop per IDMS cursor-style operation.

CORRECTION - the cursor name was derived from the RECORD.

    cursor_name_from_table(record_name)

CursorNameResolver names a cursor from the DB2 TABLE: it strips the
table suffix and appends the cursor suffix. Db2InfrastructureGenerator
calls it with table_name. This analyzer called it with VMBEFF instead
of DZBEFFTV, so it produced a DIFFERENT cursor name and a different
710/720/730 set from the ones actually generated.

Nothing failed loudly. process_paragraph_for_cursor() and
loop_for_record() simply never matched, and every caller read "".

The record is resolved to its table first. With no resolver, or with an
unmapped record, the record name is still used - the previous
behaviour - but the limitation is REPORTED rather than silent.

"""Generic flow analyzer for diagnostics.

This analyzer does not rewrite COBOL. It detects:

    - procedure paragraphs
    - cursor-like operations from parsed IDMS operations
    - output write statements, separated from IDMS update verbs
    - date / timestamp usage hints

REFACTOR - one 330-line class became six collaborators:

    flow_line_reader.py            raw records -> classified lines
    flow_paragraph_scanner.py      paragraph spans, line ownership
    flow_cursor_loop_scanner.py    IDMS operations -> CursorLoop
    flow_write_scanner.py          WRITE vs IDMS update verbs
    flow_date_scanner.py           date / timestamp tokens
    flow_diagnostics.py            the report
```

```
The public surface is UNCHANGED: analyze() still returns one
ProgramFlowAnalysis and ProgramFlowAnalyzer keeps its constructor.

"""Shared line helpers for the COBOL cleanup passes.

CORRECTION
----------
is_comment_or_blank() previously classified a line by inspecting the
STRIPPED text:

    return stripped.startswith("*") or stripped.startswith("/")

That only works when strip_sequence_numbers() has already removed the
left sequence number. When it had not - which was every comment and
page-eject line, because the old LEFT_SEQUENCE_PATTERN required
whitespace in the indicator column - a body such as "001690/" was
classified as EXECUTABLE COBOL and the terminator pass added a period.

Classification now reads column 7 of the RAW line, which is where the
COBOL standard puts the indicator, and never depends on stripping having
worked first.

================================================================================================

# LOCATION: converter/composers/cleanup/db2_date_output_cleanup.py
# ACTION: REPLACE ENTIRE FILE

"""
DB2 date output cleanup.

Converts a DB2 date host move (MOVE DA-/DT- OF DCLxxx TO UIT-/OUT- date
field) into the shared output-date realignment block before a WRITE.

CORRECTION 1 - two of three wrap shapes were handled
----------------------------------------------------
```

```
The pass matched PHYSICAL lines and recognised:

    MOVE DA-X OF DCLY TO UIT-Z          one line
    MOVE DA-X OF DCLY / TO UIT-Z        TO leads the continuation

but not:

    MOVE DA-X OF DCLY TO / UIT-Z        TO trails line 1, bare target

which is what the body wrapper emits when it breaks at a word boundary.
DB2_DATE_MOVE_ONE_LINE_PATTERN needs a target after TO;
DB2_DATE_MOVE_START_PATTERN needs the line to end at the group. Neither
matches, so a raw DB2 DATE reached the output record:

    MOVE DA-UBSECIS-479BEFF OF DCLDZBEFFTV TO
    UIT-DA-UBSEC

UIT-DA-UBSEC is PIC X(08) and received a 10-byte DD.MM.CCYY value. The
pass said nothing, in any program.

Matching is now performed against LOGICAL statements, assembled from
however many physical lines they occupy. ONE pattern covers all three
shapes, and the whole physical span is replaced.

A statement whose span contains a comment or a blank line is never
converted: the conversion replaces the span, and a swallowed comment is
a silent loss of source.

CORRECTION 2 - one diagnostic for three different outcomes
----------------------------------------------------------
A single "nothing converted" message made a successful run look like a
failure. CobolCleanupComposer is invoked TWICE per program - a known
duplication recorded in conversion_pipeline.py - so the log read:

    Cleanup: converted DB2 date move before output write.
    ...
    DB2 date output: no DB2 DATE host is moved to an output date field.

Both true, read together contradictory. Invocation 1 converted;
invocation 2 found the move already converted and reported zero
candidates.

Three outcomes are now reported distinctly:

    converted > 0                the conversion happened
    candidates > 0, converted 0  a move was seen and declined
    candidates == 0              nothing to convert, with the line count
                                 so a second idempotent pass is obvious

================================================================================

"""DCLGEN include cleanup.

Ensures an EXEC SQL INCLUDE exists for every referenced DCLGEN group that
the DCLGEN repository knows about but that is not already included.

CORRECTION 1 - third include shape
----------------------------------
This pass emitted its own three-line block with a single leading space,
placing EXEC SQL at column 9. CHK-06.07 requires Area B, column 12.

CORRECTION 2 - single-shape duplicate detection
-----------------------------------------------
_existing_includes recognised one shape only, so an include already
emitted elsewhere was added again. A duplicated DCLGEN include duplicates
every data-name in the group, which the compiler rejects. CHK-08.02
reported this as DZBFARTV x2.

CORRECTION 3 - borrowed capture group
-------------------------------------
_referenced_dclgen_tables read match.group("group") from
patterns.cobol_cleanup_patterns.DCL_GROUP_PATTERN, which does not declare
that name, raising "IndexError: no such group". It now uses
DCLGEN_GROUP_PATTERN from patterns/db2_include_patterns.py, owned
alongside this feature.

CORRECTION 4 - include injected outside WORKING-STORAGE
-------------------------------------------------------
_db2_include_insert_index scanned the WHOLE program for the last include
block, then inserted after it.

That was safe while every include lived in WORKING-STORAGE. It stopped
being safe once the SQLERROR routine adopted the copybook form:

    * SQLERROR ROUTINE.
        EXEC SQL
             INCLUDE SQLERROR
        END-EXEC.

That is an INCLUDE inside an EXEC SQL block, sitting in the PROCEDURE
DIVISION at the end of the program. The scan found it as "the last
include" and injected DZBFARTV after it, past the end of WORKING-STORAGE.
CHK-08.03 reported the include as not sitting inside WORKING-STORAGE.

The scan is now bounded: it stops at LINKAGE SECTION or PROCEDURE
DIVISION, whichever comes first, and falls back to inserting at that
boundary.

"""
Initialize-before-output cleanup.

Ensures an INITIALIZE of the output record appears immediately before the
FIRST output-field population MOVE preceding a WRITE, and removes any
duplicate INITIALIZE for that record inside the population block.

CORRECTION - population MOVEs were matched on PHYSICAL lines
------------------------------------------------------------
_line_targets_output_field() recognised two wrap shapes and missed a
third:

    MOVE src TO UIT-X             matched
    MOVE src / TO UIT-X           matched
    MOVE src TO / UIT-X           MISSED

The third is what the body wrapper emits when it breaks at a word
boundary, leaving TO as the last token of line 1 and a bare target on
line 2. Neither pattern can see it: line 1 has nothing after TO, line 2
has no TO at all.

Consequence in a production program:

    MOVE AM-CNSTK-479BEFF  OF DCLDZBEFFTV TO
    UIT-AM-CN-STOCK
    MOVE AM-CNDSTK-479BEFF OF DCLDZBEFFTV TO
    UIT-AM-CND-STOCK
    INITIALIZE UITRECORD          <- inserted here
    MOVE WS-NR-CIO-CRE TO UIT-NR-CIO-CRE

Both amounts were zeroed in every written record, silently.

Matching is now performed against LOGICAL statements, assembled from
however many physical lines they occupy, and the insertion point is the
FIRST PHYSICAL LINE of the first matching statement.

# ACTION: REPLACE ENTIRE FILE

"""Output write placement cleanup.
```

```
An IDMS child-set loop converts to:

    PERFORM <open-child>
    PERFORM <fetch-child> UNTIL <eoc> OR SW-STATUS-D = 'Y'
    PERFORM <close-child>

The per-row paragraph performed from the child FETCH paragraph decides the
row status only. A guarded output WRITE belongs in the PARENT paragraph,
after the child cursor has been closed, because the decision is not final
until every child row has been seen.

Left inside the per-row paragraph, a guarded WRITE fires again for every
later matching child row and multiplies the output file.

Manual reference shape produced by this pass:

    PERFORM <close-child>

    IF NOT SW-STATUS-D = 'Y'
       IF <status-field> = '<value>'
          PERFORM <write-paragraph>
       END-IF
    END-IF

This pass moves lines only. It never rewrites a condition, a MOVE or a
WRITE, and it does nothing at all when the shape is not recognised:

  1. locate child FETCH paragraphs (number >= CHILD_FETCH_MINIMUM_NUMBER),
  2. locate the row paragraph each one performs under WHEN ZERO,
  3. locate the PERFORM <nnn>-CLOSE-<cursor> line in the parent paragraph,
  4. lift a trailing IF ... WRITE ... END-IF block out of the row paragraph,
  5. re-indent it and insert it after the child CLOSE, wrapped in the
     early-stop guard when the parent loop uses the early-stop flag.

DEPENDENCY
----------
Step 2 reads what CursorRepair.bind_fetch_to_business writes. The binder
runs earlier (conversion_pipeline stage 'guarantee_cursor_close'), and
until it has bound WHEN ZERO to a business paragraph there is nothing
here to read. That case is now REPORTED rather than passed over in
silence - a silent refusal here cost a full debugging cycle.

No program, paragraph, record, table, cursor or host variable name is
hardcoded. Regex lives in patterns/cobol_cleanup_patterns.py, constants in
rules/cobol_cleanup_rules.py.

# ACTION: REPLACE ENTIRE FILE

"""
Paragraph sentence termination cleanup.

A COBOL paragraph is one or more sentences. When an earlier cleanup pass
inserts or lifts a block, the paragraph can be left ending on a bare scope
terminator:

    WRITE UITRECORD
    END-IF                  <- no period
    /
    710-OPEN-DZBEFFC1.

The sentence then runs into the next paragraph header and the compiler
```

```
rejects the program.

This pass finds the last executable line of every paragraph in the
PROCEDURE DIVISION and appends the sentence terminator when it is missing.
Comment, page-eject and blank lines are skipped, and a line that already
ends the sentence is never touched.

Runs last in CobolCleanupComposer, so it also covers blocks relocated by
OutputWritePlacementCleanup.

No program, paragraph, record, table, cursor or host variable name is
hardcoded. Regex lives in patterns/cobol_cleanup_patterns.py, constants in
rules/cobol_cleanup_rules.py.

"""
Residual IDMS comment cleanup.

Removes advisory comment noise left by the IDMS->DB2 transformer, such as:
    * DB2: Removed residual IDMS control statement: IDMS-CONTROL
    * SECTION.
    * DB2: Removed IDMS FIND CURRENT statement: FIND CURRENT FFRECAB
    * DB2: IDMS record FFRECAB was not converted automatically.
    * DB2: Missing Sheet Mapping and DCLGEN metadata.
    * DB2: Restart/control logic requires manual DB2 redesign.

Safety:
- Only comment lines are removed (never executable code).
- A CONTINUE. left after a removed IDMS statement is removed only when it is
  redundant (another executable statement follows in the same block and the
  CONTINUE. is not the sole statement of an IF/ELSE/WHEN/EVALUATE branch).

# LOCATION: converter/composers/cobol_cleanup_composer.py
# ACTION: REPLACE ENTIRE FILE

"""
COBOL post-conversion cleanup composer.

Applies only safe post-conversion COBOL cleanup passes:
- Remove residual IDMS conversion comment noise (+ redundant CONTINUE).
- Replace residual IDMS ERROR-STATUS loop control with DB2 flag control.
- Declare SW-STATUS-D only when needed.
- Add SW-STATUS-D early stop to nested child cursor fetch loops.
- Move a guarded output write out of the child-row paragraph to the parent
  paragraph, after the child cursor CLOSE.
- Add INITIALIZE before output-record population.
- Convert DB2 date host fields to output numeric date format before WRITE.
- Ensure DCLGEN INCLUDE exists when a DCLGEN group is referenced.
- Close any paragraph sentence left unterminated by an earlier pass.

No program names, table names, record names, or business-specific fields
are hardcoded. Exposes the accumulated messages list for conversion_service.

Pass ordering notes
-------------------
`OutputWritePlacementCleanup` must run AFTER `ChildFetchEarlyStopCleanup`,
```

```
because it reads the early-stop flag from the child fetch loop to decide
whether the relocated block needs the `IF NOT SW-STATUS-D = 'Y'` guard, and
BEFORE `InitializeBeforeOutputCleanup` and `Db2DateOutputCleanup`, so those
two passes see the write block in its final position.

`ParagraphTerminatorCleanup` runs LAST. Any pass that inserts or lifts a
block can leave a paragraph ending on a bare scope terminator, which makes
the sentence run into the next paragraph header and the compiler reject the
program. This pass is the final guard for that.

class CobolFormatter:
    """
    Preserve-first COBOL formatter.

    This formatter intentionally does NOT re-indent or restructure the full
    COBOL program.

    Reason:
    - The original IDMS COBOL source is the authority for manual style.
    - The converter must preserve existing indentation, comments, sequence-like
      lines, paragraph spacing, and business-flow layout.
    - Only generated DB2 blocks should be inserted or normalized by generators
      and composers.

    This class therefore performs only safe text cleanup:
    - Normalize Windows/Unix line endings.
    - Remove trailing spaces.
    - Limit excessive blank lines.
```

```
    - Ensure one final newline.

    It must not:
    - Strip sequence numbers.
    - Re-indent PROCEDURE DIVISION.
    - Reformat original business logic.
    - Move paragraphs.
    - Add or remove periods.
    - Change field references.

"""Safety-first placement for generated row counters.

CORRECTION - counter declared inside an output record
-----------------------------------------------------
Placement previously took the FIRST 01 group in WORKING-STORAGE. On a
program whose first group is the output record

    01  REC-FORM.
        05  F-FORM                PIC X(478).

that produced

    01  REC-FORM.
        05  WS-NB-OUTPUT-COUNT    PIC 9(7) COMP-3 VALUE ZEROES.
        05  F-FORM                PIC X(478).
```

```
shifting every byte of a fixed-length record. Every written record was
corrupted, silently.

Resolution order
----------------
1. reuse the generated counter group when a previous run made it,
2. otherwise reuse the LAST 01 group that is provably a work area,
3. otherwise create a dedicated 01 group at the WORKING-STORAGE boundary.

A record layout can never gain a field, in any branch.

# ACTION: REPLACE ENTIRE FILE

"""Counter declaration composer.

Declares every row counter the PROCEDURE DIVISION increments but
WORKING-STORAGE does not define, and appends the end-of-run totals.

Why this exists
---------------
OutputWriteParagraphComposer emits

    ADD 1 TO WS-NB-OUTPUT-COUNT

at the write call site, matching the manual reference. Nothing declared
the field, so the generated program did not compile.

Reference-driven, not table-driven
----------------------------------
The composer collects the counters actually referenced, subtracts the
names already declared anywhere in the DATA DIVISION, and declares only
the remainder. It therefore cannot declare an unused field, and cannot
miss one that a later generator starts incrementing.

Responsibility split
--------------------
This class decides WHAT to declare. CounterDeclarationWriter decides
WHERE to put it, which is where the record-corruption defect lived.

Clean Architecture
------------------
- Constants live in rules/counter_declaration_rules.py and
  rules/structural_safety_rules.py.
- Regex lives in patterns/counter_declaration_patterns.py.
- No program, record, table, cursor or host variable name is hardcoded.

"""Helpers for the cursor close-guarantee pass.

CursorCloseGuaranteeComposer decides WHICH repair path a cursor needs.
This package owns everything else.

    models.py                value objects, no logic
    message_log.py           one shared diagnostic collector
    line_utils.py            logical line read / write, condition helpers
    paragraph_index.py       paragraph discovery and navigation
    cursor_scanner.py        generated cursor paragraphs and PERFORMs
    loop_finder.py           business driving-loop discovery
    condition_normaliser.py  legacy exit test -> cursor EOC flag
    close_guarantor.py       inserts the missing PERFORM <close>
    loop_synthesiser.py      builds the manual loop shape from scratch

Import order below is dependency order, so a circular import would fail
```

```
loudly here rather than intermittently at call time.

"""Resolves the business paragraph a cursor's row logic lives in.

The composer needs this on EVERY repair path, not only on synthesis, so
it cannot stay inside LoopSynthesiser.

RESOLUTION

The business paragraph is the first NON-GENERATED paragraph that follows
the paragraph performing the cursor OPEN. In the COBOL team's manual
reference that is exactly the paragraph 720-FETCH performs.
```

```
The candidate is then VERIFIED. It must either reference the cursor's own
DCLGEN group or open a nested cursor. An unverified candidate is refused
and reported, never guessed, per CONVERSION_RULES.

No program, paragraph, record, table, cursor or host variable name is
hardcoded. Regex lives in patterns/.

FILE: converter\composers\cursor_close_guarantee\fetch_business_binder.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/composers/cursor_close_guarantee/fetch_business_binder.py
# ACTION: CREATE NEW FILE
"""Binds a generated FETCH paragraph to its business paragraph.

WHY THIS EXISTS
---------------
LoopSynthesiser._bind_fetch_to_business is documented as "used only when
no driving loop exists at all" and is reachable ONLY from synthesise().
A cursor that already has a driving loop takes the span / close-guarantor
path, which "never restructures the loop, never moves the business
paragraph" - and therefore never binds WHEN ZERO either.

The FETCH keeps CONTINUE, the business paragraph is never performed, and
the program fetches every row and does nothing with it. No diagnostic
appears because business_paragraph_unknown is also logged only inside the
synthesiser.

Binding is PATH-INDEPENDENT and belongs outside the synthesiser.

DELIBERATELY SELF-CONTAINED
---------------------------
No import of CursorLines, CursorGuaranteeLineUtils, ParagraphIndex,
CursorRepair or any rules module, because the package has shipped in two
different internal layouts. This module takes a list of physical lines
and returns one, so it cannot break when the internals change.

REFUSES RATHER THAN GUESSES
---------------------------
A candidate business paragraph must VERIFY: it either references the
cursor's own DCLGEN group, or it opens a nested cursor. An unverified
candidate is reported and the FETCH is left unchanged.
"""

"""Builds the manual OPEN / FETCH-UNTIL / CLOSE shape from scratch.

Used only when no driving loop exists at all. Three edits, applied so
that no earlier index is invalidated by a later one:

    1. bind the FETCH paragraph WHEN ZERO branch to the business
       paragraph that used to carry the OBTAIN NEXT,
    2. delete every orphan repeat PERFORM <fetch>, highest index first,
    3. replace the priming PERFORM <fetch>. with the driving loop and,
       when needed, the CLOSE.

Step 2 runs before step 3 because deleting a line below the priming
fetch cannot move the priming fetch, while inserting above it would move
every repeat.

FILE: converter\composers\cursor_close_guarantee_composer.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/composers/cursor_close_guarantee_composer.py
# ACTION: REPLACE ENTIRE FILE

"""Guarantees that every generated cursor is looped, driven and closed.

Runs AFTER CursorFlowComposer. A no-op for any cursor the INLINE or SPAN
strategy already handled, and a last-resort repair for every cursor they
could not correlate.

WHY THIS EXISTS
---------------
CursorFlowComposer recognises two driving-loop idioms. An LRF-expanded
program matches neither, so the program shipped as:

    PERFORM 710-OPEN-DZBFASC1.
    PERFORM 720-FETCH-DZBFASC1.        <- primes once, never loops
    ...
 BEHANDELING.
    PERFORM 720-FETCH-DZBFASC1.        <- orphan repeat fetch

with 730-CLOSE-DZBFASC1 declared but never performed and the FETCH
paragraph carrying WHEN ZERO / CONTINUE. The cursor is opened, read
twice, leaked, and no fetched row is ever processed. Required shape:

    PERFORM 710-OPEN-DZBFASC1.
    PERFORM 720-FETCH-DZBFASC1 UNTIL DZBFASC1-EOC.
    PERFORM 730-CLOSE-DZBFASC1.

with the FETCH paragraph driving the business paragraph:

    EVALUATE SQLCODE
      WHEN ZERO
           PERFORM BEHANDELING THRU BEHANDELING-EXIT

CORRECTION - WHEN ZERO BINDING WAS PATH-DEPENDENT
-------------------------------------------------
bind_fetch_to_business was reachable only from CursorRepair.synthesise_loop,
which runs on Path C alone. A cursor that already had a driving loop took
Path A or B, both of which deliberately never touch the business
paragraph, so the FETCH kept CONTINUE and the business paragraph became
UNREACHABLE. The program fetched every row and wrote nothing. Nothing was
logged either, because business_paragraph_unknown was also raised only
inside the synthesiser.

Binding now happens ONCE, before path selection, on every path.

THREE REPAIR PATHS
------------------
A. A fetch PERFORM already carries UNTIL -> INLINE already ran.
   Normalise a legacy exit condition and guarantee the CLOSE.

B. A business loop drives the paragraph that held the OBTAIN NEXT
   -> SPAN shape. Normalise its exit condition and guarantee the CLOSE.
   The in-loop fetch is REQUIRED here and is never removed.

C. No loop at all -> synthesise the shape and remove the orphan repeat
   fetch.
```

```
RESPONSIBILITY
--------------
This class owns PATH SELECTION and nothing else:

    cursor_guarantee/cursor_models.py                regex, value objects, log
    cursor_guarantee/cursor_lines.py                 logical lines, paragraphs
    cursor_guarantee/cursor_scanner.py               discovery, read-only
    cursor_guarantee/cursor_repair.py                every mutation
    cursor_guarantee/business_paragraph_resolver.py  business paragraph, read-only

Concrete module imports, not the package: a stale or partially updated
__init__.py then cannot break this composer, which is precisely the
failure mode that produced

    ImportError: cannot import name 'CONTINUE_PATTERN' from partially
    initialized module 'patterns.cursor_close_guarantee_patterns'

No program, paragraph, record, table, cursor or host variable name is
hardcoded here.
"""

"""Conservative rewrite for a SPAN driving loop.

Does exactly two things:

1. replaces the legacy exit condition with the cursor end-of-cursor flag,
2. guarantees the cursor CLOSE paragraph is performed after the loop.

It NEVER restructures the loop, never moves the business paragraph and
never deletes the in-loop FETCH. Restructuring a working span loop would
violate the business-flow preservation rule.

"""Cursor flow composer.

Two strategies, selected by the shape of the driving loop.

INLINE (unchanged, proven)
--------------------------
    PERFORM 710-OPEN-CURSOR.            PERFORM 710-OPEN-CURSOR.
    PERFORM 720-FETCH-CURSOR.     ->    PERFORM 720-FETCH-CURSOR
    PERFORM BUSINESS-PARA                   UNTIL CURSOR-EOC.
        UNTIL SQLCODE = 100.            PERFORM 730-CLOSE-CURSOR.

SPAN (older and LRF programs)
-----------------------------
    PERFORM BEHANDELING THRU BEHANDELING-EXIT
        UNTIL SQLCODE = 100.        ->      UNTIL DZBFASC1-EOC.
                                        PERFORM 730-CLOSE-DZBFASC1.

CORRECTION 1 - ungated OBTAIN NEXT cleanup
------------------------------------------
remove_leftover_obtain_next_cursor_calls() previously ran even when NO
plan had been produced, deleting the only FETCH inside the loop.

CORRECTION 2 - SPAN must not authorise the cleanup
--------------------------------------------------
The first gate accepted ANY plan, including a SPAN plan. A SPAN rewrite
keeps the loop body untouched and never emits PERFORM <fetch> UNTIL
<eoc>, so its in-loop fetch is REQUIRED. Gating on a SPAN plan therefore
reproduced the original defect: the loop ran forever because SQLCODE
never changed. Only an INLINE rewrite authorises the cleanup.

Orchestration only. Regex lives in patterns/, constants in rules/.

# LOCATION: converter/composers/cursor_guarantee/business_paragraph_resolver.py
# ACTION: CREATE NEW FILE

"""Resolves the business paragraph a cursor's row logic lives in.

WHY THE COMPOSER OWNS THIS
--------------------------
CursorRepair.bind_fetch_to_business is reachable only from
synthesise_loop, which runs on Path C. A cursor that already had a
driving loop took Path A or B, both of which deliberately never touch the
business paragraph, so the FETCH kept WHEN ZERO / CONTINUE and the
business paragraph became UNREACHABLE. Resolution therefore has to be
available before path selection, which is why it is a separate read-only
collaborator rather than a private method on the synthesiser.

RESOLUTION
----------
The business paragraph is the first NON-GENERATED paragraph that follows
the paragraph performing the cursor OPEN. In the COBOL team's manual
reference that is exactly the paragraph the FETCH performs:

        PERFORM 710-OPEN-DZBEFFC1          <- mainline
        PERFORM 720-FETCH-DZBEFFC1 UNTIL DZBEFFC1-EOC
        PERFORM 730-CLOSE-DZBEFFC1
    ...
 HOOFDVERWERKING.                          <- first non-generated after it

The candidate is then VERIFIED. It must either reference the cursor's own
DCLGEN group or open a nested cursor. An unverified candidate is reported
and refused, never guessed, per CONVERSION_RULES:

    "Do not fabricate DB2 SQL when Sheet Mapping metadata is missing."

READ-ONLY
---------
This class never mutates `lines`. Every mutation belongs to
cursor_guarantee/cursor_repair.py.

SELF-CONTAINED BY DESIGN
------------------------
It depends on CursorLines for logical() and is_comment() only, and falls
back to its own implementation when either is absent. The package has
shipped in two internal layouts; a resolver that reaches deeper would
break on the next one.

No program, paragraph, record, table, cursor or host variable name is
hardcoded here.

"""Regex, value objects and the diagnostic log. The passive parts.

WHY THE REGEX LIVES HERE
------------------------
The project rule puts regex in patterns/. This package is a documented
exception, and the exception is earned: the shared pattern module was
reachable by two paths, so the first module to request a name while it
was still executing failed with

    ImportError: cannot import name 'CONTINUE_PATTERN' from partially
    initialized module 'patterns.cursor_close_guarantee_patterns'

The defect was latent for exactly as long as the composer was never
constructed. This module imports NOTHING from the project, so no import
order can break it.

Nothing here makes a decision. No project, paragraph, record, table,
cursor or host variable name is hardcoded.

        CORRECTION 1 - only the FIRST statement after WHEN ZERO was read

        next_executable_index() returns ONE index. The generated branch
        carries the row counter ahead of the CONTINUE:

            WHEN ZERO
                 ADD 1 TO WS-NB-BEFF-COUNT      <- returned
                 CONTINUE                       <- never examined

        CONTINUE_PATTERN failed against the ADD, the loop advanced, and
        the method returned the list unchanged. Every FETCH that carries
        a counter - which is every FETCH the body builder emits, and the
        shape the manual reference uses - was unbindable, so the business
        paragraph stayed unreachable and the program wrote nothing.

        The WHOLE branch is now scanned, bounded by the next WHEN or by
        END-EVALUATE, so a CONTINUE at any depth in the branch is found
        and a CONTINUE belonging to another branch never is.

        CORRECTION 2 - five exits, no diagnostics

        span not found, no CONTINUE, already bound, nothing bound: all
        returned in silence. A refusal with no diagnostic is worse than
        no guard at all - it cost a full debugging cycle to find this.
        Every exit now reports.

================================================================================================

"""
Cursor ORDER BY cleanup composer.

This composer removes unintended ORDER BY clauses from parent/root cursor
declarations.

Generic rule:
- A cursor declaration without a WHERE clause is treated as a parent/root cursor.
- Parent/root cursor ORDER BY is removed unless explicit ordering is already
  handled upstream.
- A cursor declaration with a WHERE clause is treated as a child/dependent
  cursor and keeps ORDER BY.

This class does not hardcode cursor names, table names, record names, or
business fields.

# LOCATION: converter/composers/db2_date_comparison_composer.py
# ACTION: REPLACE ENTIRE FILE

"""DB2 date comparison composer.

Realigns DB2 date host fields before they are compared with a numeric
COBOL date field, and declares the shared date helper Working-Storage
(DA-CCYYMMDD, DA-CCYYMMDD-R, DA-DD-MM-CCYY) plus one HELP- field per
converted host.

No program, table, DCLGEN group or business field name is hardcoded.

This class owns no regex, constants or templates. It only orchestrates:

    Db2DateConditionAssembler     joins one IF across physical lines
    Db2DateFieldDetector          finds DATE operands in a condition
    Db2DateWorkingStorageManager  declares the helper fields
    Db2DateComparisonRewriter     emits realignment + rewrites the IF

CORRECTION 1 - the pass was silent when it did nothing
------------------------------------------------------
compose() returned the text unchanged and exposed no `messages`, so a
program whose date comparison could not be detected looked exactly like
a program with no dates at all. VMDZ7200 shipped comparing a 10-byte
DD.MM.CCYY host against an 8-byte CCYYMMDD field and nothing in the
conversion log said so. `messages` is now populated on EVERY path,
including the no-op path, and conversion_service._component_messages
picks it up automatically.

CORRECTION 2 - detection could not see the real condition
---------------------------------------------------------
The detector matched one physical line against a pattern that required
the DATE host to be the first token after IF AND required the literal
token PARMDATE. Both constraints are gone; see
patterns/db2_date_patterns.py.

ORDERING
--------
Working-Storage is ensured BEFORE the rewrite. The rewrite inserts lines
into the PROCEDURE DIVISION and re-scans from scratch, so the earlier
DATA DIVISION insertion cannot invalidate its indexes.

"""DB2 date comparison rewriter.

Emits a realignment block for every DB2 DATE host that takes part in a
COBOL comparison, then substitutes that host with its HELP- helper inside
the condition.

    IF (DA-CPTAFS-479BFAS OF DCLDZBFASTV < DA-ARCH-YMD
       AND DA-CPTAFS-479BFAS OF DCLDZBFASTV NOT = '00000000') OR ...

becomes

    * DB2: realigned 2 DB2 DATE host(s) before comparison.
    MOVE ZEROES TO DA-CCYYMMDD
    MOVE ZEROES TO HELP-DA-CPTAFS-479BFAS
    MOVE DA-CPTAFS-479BFAS OF DCLDZBFASTV TO DA-DD-MM-CCYY
    EVALUATE TRUE
      ...
    END-EVALUATE
    MOVE DA-CCYYMMDD-R TO HELP-DA-CPTAFS-479BFAS
    ... (same block per host) ...
    IF (HELP-DA-CPTAFS-479BFAS < DA-ARCH-YMD
       AND HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR ...

FIXED-FORMAT GEOMETRY
```

```
---------------------
A COBOL record is four fixed column ranges:

    1-6     left sequence
    7       indicator
    8-72    body            <- the ONLY part this pass may touch
    73-80   right sequence

Substitution happens inside the body, the body is re-padded to 65
columns, and the record is reassembled. The author's line breaks and
indentation survive exactly.

CORRECTION 1 - substitution on the raw line moved the sequence area
--------------------------------------------------------------------
The first version ran the regex over the whole 80-column record.
`DA-CPTAFS-479BFAS OF DCLDZBFASTV` is 32 characters and
`HELP-DA-CPTAFS-479BFAS` is 22, so the line shrank by 10 and the right
sequence slid from column 73 to column 63. ProcedureIndentNormalizer
then read a body with sequence digits in it and wrapped it onto two
lines.

CORRECTION 2 - the FixedFormatLineService fallback returned the raw line
------------------------------------------------------------------------
The second version called fixed_format.body(), guarded by

    except Exception: return str(line).rstrip()

The guard fired and returned the ENTIRE record as if it were the body.
That body did not fit 65 columns, replace_body_wrapped() wrapped it, and
the right-sequence digits were split off as a trailing token, producing

    002610        AND 0
    002620        HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR 0

Column arithmetic is now done here, directly, with no fallback that can
return something other than a body. A substitution that cannot be
represented in 65 columns leaves the line UNCHANGED: a cosmetic pass
must never corrupt source.

Rewriting logic only. Templates live in rules/db2_date_conversion_rules.py;
regex lives in patterns/db2_date_patterns.py.

# ACTION: CREATE NEW FILE

"""Assembles one COBOL IF condition out of its physical lines.

WHY THIS EXISTS
---------------
Db2DateFieldDetector and Db2DateComparisonRewriter both used to inspect a
single physical line. A hand-written COBOL condition routinely spans
several:

    IF (DA-CPTAFS-479BFAS OF DCLDZBFASTV < DA-ARCH-YMD
       AND DA-CPTAFS-479BFAS OF DCLDZBFASTV NOT = '00000000') OR
       (DA-CRFMAS-479BFAS OF DCLDZBFASTV < DA-ARCH-YMD AND
       DA-CPTAFS-479BFAS OF DCLDZBFASTV = '00000000')

A per-line matcher structurally cannot see that, so the date pass was
skipped and the program shipped comparing a 10-byte DD.MM.CCYY host
against an 8-byte CCYYMMDD field.

WHERE A CONDITION ENDS
----------------------
Scanning stops at the FIRST of:

  * parentheses balanced AND the line does not end on AND / OR / NOT AND
    the next line does not begin with AND / OR / (,
  * a line that starts a COBOL statement verb,
  * CONDITION_SCAN_LIMIT lines.

Hitting the limit is reported, never guessed around.

Read-only. Assembles and measures; rewrites nothing.

"""Detects DB2 DATE hosts that take part in a COBOL comparison.

Detection logic only. Owns no regex (patterns live in
patterns/db2_date_patterns.py) and no templates.

CORRECTION - detection was single-line and name-bound
-----------------------------------------------------
The old detector matched one physical line against a pattern that
required the DATE host to be the first token after IF AND required the
literal token PARMDATE somewhere in the condition. Any parenthesised,
compound, multi-line or differently-named comparison returned an empty
field list, so the composer's `if date_fields:` guard was False and the
whole pass was skipped without a word.

Detection now works on an ASSEMBLED condition and names no business
field: a DATE host is recognised by its DCLGEN-qualified shape, and it
counts only when the condition also carries a comparison operator.

================================================================================

"""
Final COBOL fix composer.

Applies the remaining generic post-conversion COBOL fixes:

1. Program-name synchronization.
2. DB2 date format correction.
3. Cursor SELECT/FETCH minimization.
4. Update-program final cleanup.
5. Procedure Division Area B alignment.
6. Readable IF / ELSE / END-IF and EVALUATE indentation.
7. STRING block manual-style formatting.
8. Final manual-style resequencing.

This composer owns no regex or constants. It orchestrates focused services.
It does not hardcode business names, DB2 tables, columns, DCLGEN groups,
host variables, or program names.

# LOCATION: converter/composers/fixed_format_line_composer.py
# ACTION: REPLACE ENTIRE FILE

"""Per-line composition: parse, area-body, wrap, sequence, compose.

Depends on the host class for ``self.line_parser``, ``self.body_formatter``
and ``self.wrapper``. Layout constants and patterns are external.

CORRECTION - width was measured in BYTES
----------------------------------------
_compose_line previously ended with:

    line_bytes = final_line.encode('utf-8')
    if len(line_bytes) > TOTAL_WIDTH:
        line_bytes = line_bytes[:TOTAL_WIDTH]
        final_line = line_bytes.decode('utf-8', errors='ignore')
    final_bytes = final_line.encode('utf-8')
    if len(final_bytes) < TOTAL_WIDTH:
        final_line = final_line + (' ' * (TOTAL_WIDTH - len(final_bytes)))

A record carrying one non-ASCII character is 80 CHARACTERS but 81 BYTES
in UTF-8, so this:

    1. truncated to 80 bytes, severing the trailing byte,
    2. decoded with errors='ignore', SILENTLY DROPPING the severed
       character - the record is now 79 CHARACTERS,
    3. padded to 80 BYTES, which the 2-byte character already satisfied,
       so no padding was added.

FixedFormatLineParser then rejected the 79-character record as
unsequenced and its own sequence area was written into the body of a new
record:
```

```
    000380 000380* 2004/12 REPRENDRE N DE TITRE EN OUTPUT (12 POS

A COBOL source record is 80 CHARACTER POSITIONS. Encoding is the writer's
concern, not this composer's.

"""Fixed-format COBOL line parser.

Responsibilities:
  - Parse already sequenced 80-column COBOL records.
  - Parse unsequenced COBOL lines.
  - Strip old left and right sequence numbers.
  - Preserve COBOL body indentation.
  - Detect indicator column values.

CORRECTION 1 - the length test was fatal
----------------------------------------
_is_fixed_format_line required len(text) >= TOTAL_WIDTH and digits at
columns 73-80. A record short by even ONE character was therefore
classified as UNSEQUENCED, and its entire content - its own sequence
area included - was written into columns 8-72 of a new record:

    000380 000380* 2004/12 REPRENDRE N DE TITRE EN OUTPUT (12 POS

A record goes short for ordinary reasons: a blank right sequence, a
truncated line, or a multi-byte character severed upstream.

"Is this record sequenced" and "does it carry a right sequence" are now
two separate questions. Coupling them is what tied the two failures
together.

CORRECTION 2 - rstrip() destroyed the body padding
--------------------------------------------------
parse_line() and replace_body_preserving_sequence() opened with

    text = str(line or "").rstrip()

Trailing blanks are not decoration: they are what hold the right sequence
at column 73. A record whose columns 73-80 are blank was stripped back to
column 72, failed the width test, and fell through to the loose path -
where its sequence area became body text. Only the LINE ENDING is removed
now.

CORRECTION 3 - geometry was imported from a composer
----------------------------------------------------
RIGHT_SEQUENCE_START and RIGHT_SEQUENCE_END were imported from
converter.composers.retrieval_commit_cleanup_composer. Column geometry
belongs in rules/, and a parser importing a composer is a layering
inversion that will deadlock as a circular import the moment that
composer imports anything from this package.

"""Late DB2 date output conversion.

Re-runs Db2DateOutputCleanup after the output write block has reached its
FINAL location.

Why a second run is needed
--------------------------
Db2DateOutputCleanup lives inside CobolCleanupComposer. Its documented
ordering places it after OutputWritePlacementCleanup so it can see the
write block in its final position.

That held while the block merely moved between paragraphs. It no longer
holds: OutputWriteParagraphComposer now EXTRACTS the block into a new
WRITE-<record> paragraph much later in the pipeline. The date converter
has already finished by then, so a DB2 date host field is moved straight
into the output record without the CCYYMMDD realignment:

    MOVE DA-UBSECIS-479BEFF OF DCLDZBEFFTV TO UIT-DA-UBSEC

UIT-DA-UBSEC then receives the raw DB2 external date form rather than the
numeric form the downstream file expects. That is silent data corruption,
not a formatting defect.

Idempotence
-----------
A second run is safe. The converter only matches a MOVE whose source is a
DB2 date host qualified by a DCLGEN group. After conversion the move
reads

    MOVE DA-CCYYMMDD-R TO UIT-DA-UBSEC

which carries no DCLGEN qualifier and therefore cannot match again.

"""Structural safety gate for the output write extraction.

DEFECT THIS CLOSES
```

```
------------------
Extraction splices the call site in place of the IF BODY, cutting at
if_index + 1. That is correct only when the whole condition lives on the
IF line. A hand-written guard frequently spans lines:

    IF (DA-CPTAFS OF DCL... < DA-ARCH-YMD
        AND DA-CPTAFS OF DCL... NOT = '00000000') OR
        (DA-CRFMAS OF DCL... < DA-ARCH-YMD AND
        DA-CPTAFS OF DCL... = '00000000')
        PERFORM ...

Cutting at if_index + 1 leaves the IF with no condition tail and moves
the tail into the new paragraph, where it begins with a dangling AND.
The program does not compile.

CORRECTION - the gate was PROGRAM-WIDE
--------------------------------------
It refused every extraction in a program when ANY PROCEDURE DIVISION IF
carried a multi-line condition, including conditions with no WRITE
anywhere near them. One program refused on a two-line business status
test while its real write guard, IF WS-STATUS = 'C', was a single line
and entirely safe to cut. Three of six programs lost their
WRITE-<record> paragraph, and with it the output counter that is added
at the call site the extraction creates.

Rule A1 in rules/structural_safety_rules.py is narrower than the old
gate: an extraction must never cut between an IF keyword and the end of
ITS condition. The scope is one candidate block, not the program.

API
---
    blocks_candidate(lines, if_index)   DECIDES. One candidate.
    condition_size(lines, if_index)     measures one condition.
    blocks_extraction(text)             REPORTING ONLY. Whole program.
    widest_condition(text)              REPORTING ONLY. Whole program.

The two program-wide methods are retained because they characterise a
program in one call, and because tests assert them. NOTHING decides on
them. Deciding on them is the defect above.

----------------
- PROCEDURE DIVISION only.
- Exactly ONE WRITE per block. Two writes is a business decision.
- REFUSES for the whole program when any guard condition spans lines.
- Lines are moved and re-indented, never edited.

Ordering
--------
AFTER composers["feedback_cleanup"] (relocates the guarded block) and
AFTER composers["fixed_format"] (so lines can clone a sequence area).
BEFORE FinalSequenceResequencerService.

Responsibility split
--------------------
    output_write/output_write_line_utils.py     line inspection
    output_write/output_write_scanner.py        boundaries
    output_write/output_write_guard.py          structural safety gate
    output_write/output_write_block_finder.py   candidate discovery
    output_write/output_write_eligibility.py    accept / refuse
    output_write/output_write_renderer.py       rendering
    output_write/output_write_extractor.py      line replacement

This class owns iteration and diagnostics. Nothing else.

# ACTION: REPLACE _extract_once

    def _extract_once(self, lines: list[str]) -> bool:
        """Extract the INNERMOST eligible block. True when one was taken.

        CORRECTION - the first eligible candidate was taken, and
        candidates arrive outermost first.

        Extraction moves the candidate's BODY, which starts at
        if_index + 1. Taking the outer guard therefore moved the inner
        guard into the new paragraph:

            IF NOT SW-STATUS-D = 'Y'
               PERFORM WRITE-UITRECORD
               ADD 1 TO WS-NB-OUTPUT-COUNT     <- fires unconditionally
            END-IF.

         WRITE-UITRECORD.
            IF WS-STATUS = 'C'                 <- the real write decision
               ...
               WRITE UITRECORD
            END-IF.

        The counter then measured ATTEMPTS, not writes, and
        output_write_paragraph_rules.py requires the opposite: the count
        is taken at the call site precisely so it reflects every guard
        decision.

        Every enclosing guard must stay at the call site. The innermost
        eligible candidate is the one whose body is pure population, so
        candidates are now ranked and the deepest is taken.

        Three gates, cheapest and least noisy first:

          1. ELIGIBILITY - exactly one WRITE. A block with none is an
             ordinary IF and is dismissed in silence.
          2. CONDITION INTEGRITY - this block's OWN guard must fit one
             line, because the cut is at if_index + 1.
          3. EXTRACT the deepest survivor.

# LOCATION: converter/composers/procedure_indent_normalizer.py
# ACTION: REPLACE ENTIRE FILE

"""Procedure Division indentation normalizer.

Runs late (before final resequence) to give PROCEDURE DIVISION executable
statements a consistent, DEPTH-AWARE Area-B indentation. Fixes irregular
indents produced by different generators (SQL MOVES, EXEC SQL, timestamp
MOVES, etc.) and indents IF / EVALUATE / PERFORM .. END-PERFORM bodies
progressively to match the manual COBOL standard.

Safe scope
----------
- Only PROCEDURE DIVISION.
- Only executable statement lines (space indicator in column 7).
- Never touches comments ('*' / '/'), debug lines ('D'), continuation
  lines ('-'), Area-A paragraph/section headers, or the DATA and other
  divisions.
- Preserves the 80-column frame: rewrites only columns 8-72 body indent;
  left seq (1-6) and right seq (73-80) untouched.
- EXEC SQL ... END-EXEC blocks keep the flat SQL body indent, not depth.
```

```
CORRECTION - silent truncation
------------------------------
This class previously carried a PRIVATE copy of the fixed-format geometry
that had drifted from the shared service:

    @staticmethod
    def _is_fixed_line(line):
        return (len(text) >= 80 and text[:6].isdigit()
                and text[72:80].isdigit())

    @staticmethod
    def _rebuild(left, new_body, right):
        body_area = new_body[:65].ljust(65)      # <-- silent truncation
        return f"{left[:6].zfill(6)}{' '}{body_area[:65]}{right[:8]}"

Two defects followed.

1. _is_fixed_line demanded a full 80 columns AND a numeric right
   sequence, so a short page-eject line such as '001690/' was misparsed
   and its sequence number could reach the COBOL body.

2. _rebuild truncated any body past column 72 without telling anyone.
   Because this normalizer is the LAST content pass in the pipeline, it
   is how

       MOVE NR-IDGOOD-479EVEF OF DCLDZEVEFTV    TO WS-NR-ID-GOOD

   was written out as

       MOVE NR-IDGOOD-479EVEF OF DCLDZEVEFTV    TO WS-NR-ID-GO

   producing an undefined data name that the compiler rejects.

Geometry is now delegated entirely to FixedFormatLineService. A re-indent
that no longer fits is WRAPPED onto a continuation line; if even that is
impossible the original line is kept unchanged. A cosmetic pass must
never destroy a statement.

TEMPORARY INSTRUMENTATION
-------------------------
A four-line IF condition reached the generated file merged into two
truncated lines. This pass processes ONE line at a time and has no join
path, so the merge must happen upstream. DUMP_INTERMEDIATE writes the
text this pass receives and the text it returns, which settles the
question in one run. Set it to False, or delete the three marked blocks,
once the culprit is fixed.

Clean Architecture
------------------
- Constants live in rules/procedure_indent_rules.py.
- Regex lives in patterns/procedure_indent_patterns.py.
- No program, paragraph, record, table, cursor or host variable name is
  hardcoded.

"""Rewrites the MOVE statement and expands the target field.

CORRECTION 1 - the expanded header lost its indent

    Generated output read

        000820 01  REC-FORM.
        000830 05  F-FORM.        <- column 8, Area A

    Level 01 and 77 start in Area A; levels 02-49 must start in Area B.
    The target's own body indent is now reused for the header, the
    layout block and the remainder FILLER, so the expansion sits exactly
    where the field it replaces sat.

CORRECTION 2 - the MOVE continuation lost its indent

        MOVE CT-RKTGDSV-479BFAS OF DCLDZBFASTV TO
        CT-RK-TGDSV OF VMBFAS          <- same column as MOVE

    The generator's own leading spaces are preserved, so the statement
    reads as one MOVE.

CORRECTION 3 - the record is a PREFIX of the target

    478 - 432 = 46 trailing bytes are declared as FILLER, so the record
    keeps its length and no following byte shifts.

"""Renders the materialised record as COBOL data description entries.

Orchestration only. Every column rule lives in the geometry class and
every template in one of the two renderers:

    record_layout_geometry.py      columns, indents, widths, levels
    record_entry_renderer.py       group + elementary entries
    record_redefines_renderer.py   REDEFINES, inline or wrapped

Public API is unchanged, so record_block_writer.py needs no edit.

CORRECTION 3 - the record is a PREFIX of the target field

    05  F-FORM            PIC X(478).      <- the field being replaced
        06  VMBFAS.                        <- 432 bytes
        07 ...
        06  FILLER        PIC X(46).       <- the remainder, declared here

    Without the remainder FILLER the record silently shortens and every
```

```
    following field shifts left.

"""Fixed-format geometry for generated data description entries.

Pure arithmetic. No templates, no COBOL text, no plan knowledge - every
method takes strings and numbers and returns strings and numbers, so the
column rules can be reasoned about and tested in one place.

THE RULES THIS CLASS ENFORCES

  * levels 02-49 start in Area B, column 12 or later,
  * a body never reaches column 72,
  * a name is padded before its PICTURE, and the padding shrinks rather
    than letting the line overflow,
  * an entry carries EXACTLY ONE terminating period,
  * nesting indent is capped, so no depth can push a picture off the end.

CORRECTION 2 - nesting overflowed the body

    A fixed 4-space step put a level-11 entry at column 29 and pushed
    'PIC S9(3) COMP-3.' past column 72, so the emitter degraded to an
    unaligned fallback. The step is 2 spaces and the depth is capped.

CORRECTION 4 - double period on every group entry

    GROUP_ITEM_TEMPLATE ends in a period, ELEMENTARY_ITEM_TEMPLATE does
    not. Appending one unconditionally produced '06  VMBFAS..', which
    the compiler rejects. terminate() never assumes what a template did.

"""Decides whether one record may be materialised.
```

```
Every gate REFUSES rather than guesses. A refusal leaves working COBOL
and a diagnostic; a guess corrupts a fixed-length output record.

CORRECTION A - the length rule was equality

    The IDMS record is a PREFIX of the output field, never equal to it:

        05  F-FORM   PIC X(478).
            06  VMBFAS.            <- 432 bytes

    |432 - 478| = 46 > 0 guaranteed refusal on every run. The layout may
    be SHORTER; only LONGER is fatal, because that shifts every byte
    after it.

CORRECTION B + C - unmapped subordinates and FILLER blocked

    A field is missing ONLY when it carries a real DB2 column that DCLGEN
    does not define. No column at all means COBOL filler or the
    breakdown of a mapped parent.

"""Renders the field-by-field population of a materialised record.

A non-date column becomes a single MOVE. A DB2 DATE column becomes the
manual reference conversion block, using the shared date staging fields
that Db2DateComparisonComposer already declares.

CORRECTION - the continuation line lost its indent

        MOVE CT-RKTGDSV-479BFAS OF DCLDZBFASTV TO
        CT-RK-TGDSV OF VMBFAS          <- same column as the MOVE

    The indent used to live in MOVE_TARGET_TEMPLATE's leading spaces,
    which an unapplied rules override or a later indent pass can flatten.
    It now lives in CODE, applied here, so it cannot be lost.

    A MOVE short enough to fit on one line is emitted on one line, which
    removes the continuation problem entirely for most fields.

"""Locates whole-record MOVE statements and their target fields.

Read-only. Finds sites; rewrites nothing. Sizing lives in
record_picture_sizer.py and the value objects in record_sites.py, so
this class is nothing but two scans.

CORRECTION 1 - first-match-wins

    The original scanner returned the FIRST whole-record MOVE and the
    composer abandoned the whole pass on any refusal. A LINKAGE date
    field matched first, had no Sheet Mapping rows, and the real record
    MOVE was never examined - it then reached the structural safety pass
    and was commented out.

    find_move now takes the set of pairs already visited and returns the
    next unvisited one, so the caller can iterate and a refusal stays
    local to one record.

"""Sizes a COBOL PICTURE clause in stored bytes.

Pure measurement. Given a data description line it answers one question:
how many bytes does this entry occupy? Getting that wrong silently
shifts every field of a fixed-length record.

WHY THIS MODULE OWNS NO REGEX
-----------------------------
The project rule puts regex in patterns/. This module is the documented
exception, and the exception is earned:

    PIC 9999    -> 4      correct
    PIC 9(7)    -> 1      wrong
    PIC X(478)  -> 1      wrong

PICTURE_SYMBOL_PATTERN captures the symbol and exposes no repeat group,
so every clause written with (n) collapsed to the count of literal
symbols. F-FORM measured 1 byte, the length guard refused a 432-byte
VMBFAS layout as "longer than the 1 byte F-FORM declares", and roughly
400 lines of generated output were discarded on every run.

Three separate attempts to fix that through the shared pattern module
produced identical wrong answers, because a pattern this module cannot
see is a dependency this module cannot verify. Counting repeat groups is
character arithmetic, not pattern matching, so it is done here, in full
view, where a unit test pins every branch.

No regex. No imports. No hidden behaviour.
"""

"""Turns one Sheet Mapping row into a RecordFieldPlan.

Sheet Mapping is the authority for the COBOL layout (cobol_zone,
idms_pic_clause) and the DB2 column. Nothing is invented: a cell the
sheet does not supply becomes an empty string, never a guess.

CORRECTION - the byte fallback trusted one repeat pattern

    _bytes fell back to PICTURE_REPEAT_PATTERN, which only sees an
    explicit '(nnn)'. That reads 'X(10)' correctly but returns 3 for
    'XXX' and 13 for 'S9(13)V99' (the trailing V99 is invisible).

    The fallback now counts every stored symbol with its repeat, the
    same way RecordMoveScanner sizes a target PICTURE. The sheet's own
    length column still wins when it is present.

================================================================================================

# LOCATION: converter/composers/record_materialisation_composer.py
# ACTION: REPLACE ENTIRE FILE
"""Materialises IDMS records referenced by whole-record MOVE statements.

    MOVE VMBFAS TO F-FORM
        -> 05  F-FORM.
               06  VMBFAS.
                   07 ...
               06  FILLER             PIC X(46).
           MOVE <host> TO <field> OF VMBFAS   ... one per mapped field

CORRECTION E - first-match-wins (the defect that masked all the others)

    find_move returned the FIRST whole-record MOVE and compose() ran
    'return str(text)' on any refusal, abandoning the entire pass. A
    LINKAGE date field (DATE8-LS) matched first, had no Sheet Mapping
    rows, and VMBFAS was never examined - it then reached the structural
    safety pass and was commented out.

    Every whole-record MOVE is now visited, and a refusal is LOCAL.

CORRECTION F - a refusal was invisible

    Each refusal already carried its reason, but the reason landed in
    the Info band among thirty-odd other lines, so several runs went by
    with nobody able to say WHY the record did not materialise.

    Three changes close that:

      * the measured target length is reported on every attempt, so a
        length refusal needs no code read to interpret,
      * every refusal reason is collected and re-emitted as ONE summary
        line naming the records,
      * rules/validation_display_rules.py lifts refusal wording into the
        Warnings band.

Orchestration only:

    record_move_scanner.py              finds the sites
    record_materialisation_guard.py     decides refusals
    record_block_writer.py              writes the replacement lines

FILE: converter\composers\retrieval_commit_cleanup_composer.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/composers/retrieval_commit_cleanup_composer.py
# ACTION: REPLACE ENTIRE FILE
"""Removes a COMMIT block from a retrieval program.

Safety net only. ControlStatementConverter is the authority and now
honours EMIT_COMMIT_IN_RETRIEVAL. This pass catches a COMMIT that
arrives by any other route: one already present in the legacy source, or
one emitted by a generator that does not read the flag.

Scope and safety
  - PROCEDURE DIVISION only.
  - Runs ONLY when the program is retrieval.
  - Removes the whole EXEC SQL ... COMMIT ... END-EXEC block plus the
    MOVE 'COMMIT' TO SQL-LOCATION line that precedes it.
  - Leaves a comment so the removal is visible, never silent.
  - Does nothing at all when the shape is not recognised.

CORRECTION 1 - the removal could empty a paragraph
--------------------------------------------------
The replacement is a COMMENT, which is not executable. In one converted
program the paragraph survived only because a CLOSE followed:

    <paragraph>.
    * DB2: COMMIT removed; retrieval program is read-only.
        CLOSE <file>.               <- rescued it

A paragraph containing ONLY the COMMIT block would have been left with a
comment and nothing else, and the compiler rejects an empty paragraph.
The pass now looks FORWARD for the next executable statement and emits
CONTINUE. when it meets a paragraph, section or division boundary first.

CORRECTION 2 - a short record flipped a boundary decision
---------------------------------------------------------
strip_sequence_numbers() recognises a right sequence only in columns
73-80 of a FULL 80-column record. A line short by even one character
keeps its trailing digits, so a paragraph header read as

    <paragraph>.                            0074700

which contains a space and was therefore classified as a STATEMENT. The
emptiness scan then concluded the paragraph was still populated and the
guard never fired. _logical() now drops a trailing sequence-length digit
run defensively.

CORRECTION 3 - the generated record was 79 columns
--------------------------------------------------
The rendered body carries the indicator, so it spans columns 7-72, which
is 66 characters, not 65. At 65 the record came out one column short and
the right sequence landed in column 72.
```

```
The widths are now DERIVED from the column boundaries rather than
written as separate literals, so the three cannot drift apart.

No program, record, table, cursor, paragraph or host variable name is
hardcoded. Constants live in rules/retrieval_commit_cleanup_rules.py.

# LOCATION: converter/composers/sequence_artifact_cleanup_composer.py
# ACTION: CREATE NEW FILE

"""Sequence artifact cleanup composer.

Removes lines whose COBOL body is nothing but a leaked source sequence
number, and repairs the sentence the removal exposes.

Symptom
-------
    002480     STOP RUN.
    002490     001690/.                <-- not COBOL
    002500 HOOFDVERWERKING.

The original source carried a page-eject line:

    001690/

A formatting pass that did not recognise the short, unsequenced form
treated the WHOLE line as COBOL text. The left sequence number and the
indicator became the body, and the paragraph terminator pass then added
a period, producing '001690/.'.

Consequences if left in place
-----------------------------
- The compiler rejects the statement.
- OutputWritePlacementCleanup cannot match a trailing
  IF ... WRITE ... END-IF block, because the artifact sits between the
  END-IF and the paragraph boundary. The guarded output write is then
  never relocated out of the child-row paragraph, and the WRITE fires
  once per fetched child row instead of once per parent row.

Why this runs late
------------------
The artifact is produced AFTER CobolCleanupComposer, by one of the
layout passes. Dropping it inside ParagraphTerminatorCleanup is too
early. This composer therefore runs immediately after
composers["fixed_format"], where every line is sequenced and no further
pass will reintroduce the shape.

Repair
------
Removing the artifact can leave the preceding statement unterminated,
because the artifact was carrying the period:

    003040     END-IF
    003050     002190/.        <-- removed

This composer therefore walks back to the last executable line of the
paragraph and restores the sentence terminator when it is missing.

Clean Architecture
------------------
- Constants live in rules/sequence_artifact_rules.py.
- Line geometry and artifact detection come from FixedFormatLineService.
- No regex is defined here.
- No program, paragraph, record, table, cursor or host variable name is
  hardcoded.

"""Final structural safety pass. COMMENT-ONLY, never deletes.

A2 - orphaned whole-record reference
    MOVE VMBFAS TO F-FORM survives after COPY IDMS LR is removed, so
    VMBFAS is an undefined data-name.

A4 - unreachable statement after a paragraph EXIT
    A statement between EXIT. and the next paragraph header can never
    run and sits outside any paragraph.

CORRECTION 1 - EXIT. matched the paragraph-header pattern
    The exit test now runs BEFORE the header test.

CORRECTION 2 - long markers lost their sequence numbers
    Comments are wrapped through emit().

CORRECTION 3 - comment lines were never recognised
    _is_comment() tested FixedFormatLineService.logical(), which returns
    columns 8-72 only. The '*' indicator lives in column 7, so it was
    never in the string being tested and every comment was treated as
    executable. Classification now reads the RAW line.

CORRECTION 4 - a tracking bug could comment out the whole program
```

```
    With CORRECTION 1 and 3 missing, the A4 guard stayed armed past the
    generated cursor block and commented 60+ lines. A hard cap now
    reverts the entire pass when it matches more lines than real
    unreachable code ever spans.

ENCODING: utf-8
================================================================================

"""
Record-level Option B composer (IDMS-source-seeded, column-confirmed).

A record is UNMAPPED when ColumnNameResolver.columns_for_record(record)
returns an empty list. Covers the case where a Sheet Mapping ROW/table
exists (e.g. FFRECAB -> DZ01RSTB) but has zero usable columns.

For an unmapped record every referencing line is commented (record-level):
  - lines qualified with 'OF/IN <record>', AND
  - bare lines that move into a field of the record's naming family
    (the '-FF' family for FFRECAB, e.g. NS-SET-FF, NS-REC-FF-IN, NR-KY-FF).

Production comment layout (each emitted line is exactly 80 columns):
  - columns 1-6  : left sequence number (preserved from original line)
  - column 7     : '*' comment indicator
  - columns 8-72 : COBOL body (original indentation preserved)
  - columns 73-80: right sequence number (preserved from original line)

If a comment body does not fit in columns 8-72 it is wrapped onto the next
comment line (standard COBOL comment continuation), each still 80 columns.

# LOCATION: converter/composers/update_sql_cleanup_base.py
# ACTION: CREATE NEW FILE (this replaces update_program_feedback_shared.py)

"""
Shared base for update-program SQL cleanup composers.

Generic rules:
- Sheet Mapping is authority for DB2 tables and columns.
- DCLGEN is authority for host variable spelling.
- Do not hardcode program names, table names, columns, or host variables.
- For CALC/update flows, prefer DB2 primary-key metadata.
```

```
- Avoid broad WHERE clauses when a narrower DB2 identity key is available.

Source-field resolution is deterministic (delegated to the Sheet Mapping
repository). No fuzzy / similarity matching.

This base composes focused mixins so subclasses keep the exact same inherited
interface (self._logical, self._db2_primary_key_columns, self._set_lines,
self._column_for_source_field, ...) and the same class-level regex/constant
attributes.

================================================================================

# LOCATION: converter/composers/update_sql_cleanup_composer.py
# ACTION: CREATE NEW FILE (this replaces update_program_sql_feedback_composer.py)

"""
Update SQL cleanup composer.

Fixes update-program SQL issues:
- malformed PERFORM SQLERROR.END-IF.
- bare changed field move before MODIFY.
- unnecessary OBTAIN CALC SELECT.
- broad MODIFY UPDATE / WHERE (rewritten to changed field + audit fields).

Composite key WHERE includes all PK / CALC key fields; FK / FOREIGN columns
are never used in WHERE. No program, table, DCLGEN group, or field name is
hardcoded. Sheet Mapping decides table/column mapping; DCLGEN decides host
variable spelling. Delegates each pass to a focused helper class.
"""

[Empty file]

================================================================================================
FILE: converter\domain\models.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/domain/models.py
# ACTION: REPLACE ENTIRE FILE
"""Domain models shared by parsers, repositories, resolvers and the UI.

Dataclasses only. No parsing, no logic, no I/O, no program / record /
table / column names.

CORRECTION - a dataclass referenced a class defined below it
------------------------------------------------------------
The LRF models were appended to the END of this module while
ConversionInput, declared earlier, already carried

    logical_records: list[LogicalRecord] = field(default_factory=list)

Without lazy annotations that type is evaluated while the class body
executes, so the name did not exist yet and every import of this module
died with

    NameError: name 'LogicalRecord' is not defined

The failure surfaced through the Streamlit entry point
(app -> main_page -> main_tab -> conversion_actions -> domain.models)
but it is not a Streamlit, Python-version or environment problem: the
module cannot be imported by anything.

TWO GUARDS, deliberately both:

  1. DEFINITION ORDER - every model is declared before the model that
     references it. LRF models therefore sit ABOVE ConversionInput.

  2. LAZY ANNOTATIONS - `from __future__ import annotations` makes the
     order irrelevant to the interpreter, so a future edit that moves a
     class cannot reintroduce the same crash.

Guard 2 does NOT replace guard 1: repositories/lrf_repository.py does a
real runtime import,

    from converter.domain.models import LogicalRecord, LrfPath

so the names must exist in the module regardless of how annotations are
evaluated.

FIELD NAMES ARE A CONTRACT
--------------------------
lrf_parser.py constructs these objects and lrf_repository.py /
lrf_path_resolver.py read them by attribute. Renaming a field here
breaks those modules silently at runtime, not at import.
"""

)

__all__ = ["CursorDeclarationGenerator"]

================================================================================================
FILE: converter\generators\cursor_declaration\cursor_declaration_generator.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/generators/cursor_declaration/cursor_declaration_generator.py
# ACTION: CREATE NEW FILE
"""Generates DB2 cursor DECLARE statements - LEGACY shape.

Emits the COBOL team's manual reference layout:

    * DECLARE CURSOR FOR BEFF TABLE
    * ------------------------------
    *
        EXEC SQL DECLARE DZBEFFC1 CURSOR WITH HOLD FOR
          SELECT CO_IDPRKSK_479BEFF
               , NS_IRMOSTK_479BEFF
          FROM DZBEFFTV
          FOR READ ONLY
                 QUERYNO 254
        END-EXEC

REFACTOR - this generator re-implemented four decisions that
CursorDeclareBuilder had already corrected, and the two had DIVERGED.
It now REUSES the shared collaborators and keeps only what is genuinely
legacy: the banner and the one-line SELECT shape.

    declare_diagnostics.py       the decision record
    declare_column_ownership.py  what does this table own
    declare_order_by_planner.py  which ORDER BY entries survive
    declare_refusal.py           the DB2 WARNING blocks
    legacy_banner_builder.py     LEGACY - the comment banner
    legacy_clause_renderer.py    LEGACY - the one-line SELECT shape

CORRECTION 1 - the warnings were re-declared here.

Three templates sat as module constants while rules/ already owned
those names, and the wording had drifted ("missing DB2 table mapping."
against "no DB2 table."). Both generators now emit the same sentence
for the same refusal.

CORRECTION 2 - the ownership guard split on '=' only.

    left = condition.split("=", 1)[0]

A predicate with a KEYWORD operator - IS NULL, BETWEEN, IN, LIKE - has
no '=', so the WHOLE predicate became the "column", failed the test,
and a valid cursor was refused. DeclareOperandParser handles both forms
and strips a T.COL qualifier.

CORRECTION 3 - QUERYNO was 0-BASED.

_queryno() received enumerate()'s index, so the first cursor rendered
QUERYNO 253 while CursorDeclareBuilder rendered 254 for the same
cursor. DB2 EXPLAIN identifies a statement by QUERYNO; two generators
```

```
with two schemes cannot both be tied back to the documented access
path. Cursor order is 1-based here too.

CORRECTION 4 - a resolver failure aborted the whole block.

columns_for_table() was called bare. A thin or broken DCLGEN raised out
of generate() and no declaration at all was produced.
DeclareColumnOwnership reports and stands down.

CORRECTION 5 - the injected diagnostics list was discarded.

    def __init__(self, ..., diagnostics: list[str] | None = None):
        self.messages = diagnostics if diagnostics is not None else []
    def generate(self, specs):
        self.messages = []          <- rebinds, caller's list never filled

The caller's list stayed empty for every run. Messages are appended to
the injected list now and reset() is explicit.

CORRECTION 6 - the docstring asserted a WITHDRAWN premise.

"A cursor with NO WHERE clause is a parent/root cursor and never
carries ORDER BY" came from ONE sample. Manual reference VMDZ7200 ends
its ROOT cursor with ORDER BY NR_ID_479BFAS ASC, and
ENFORCE_ORDER_BY_RETENTION is True. This file read
PARENT_CURSOR_KEEPS_ORDER_BY directly and never consulted the master
switch. DeclareOrderByPlanner owns that decision for both generators.

CORRECTION 7 - ORDER BY entries were neither owned nor de-duplicated.

The FILLER placeholder that binds as SQLCODE -206, and the
'NR_ID ASC' / 'NR_ID DESC' pair DB2 rejects outright, both reached the
legacy output unchecked.

Clean Architecture:
- Every literal lives in rules/.
- No regex is defined in this package.
- No program, record, table, cursor or host variable name is hardcoded.

"""DISPLAY lines that identify the failing row in a FETCH error branch.

MANUAL REFERENCE

    820-FETCH, the CHILD cursor:

        WHEN OTHER
             DISPLAY 'ERROR WHILE FETCHING CURSOR DZEVEFC1'
             DISPLAY 'NR-DB-STOCK = ' NS-DBSTK-479BEFF
                                      OF DCLDZBEFFTV

    720-FETCH, the PARENT cursor:

        WHEN OTHER
             DISPLAY 'ERROR WHILE FETCHING CURSOR DZBEFFC1'

    Cursor name only. The parent has no driving key to report - it is
    the driver.

CORRECTION - the WHERE path emitted an UNQUALIFIED host.

_where_clause_diagnostic_lines() built its own one-line DISPLAY and
argued that 'CT-RKTPROD-479BEFF OF DCLDZBEFFTV' is too wide, so the
bare name must be used. Both halves of that are wrong:

  1. A foreign-key column keeps the PARENT's column name, so
     CT-RKTPROD-479BEFF is declared in BOTH DCLDZBEFFTV and
     DCLDZEVEFTV. The bare name is NOT UNIQUE and the program does not
     compile. The manual reference wraps 'OF DCLDZBEFFTV' onto a
     continuation line for exactly this reason.

  2. "Too wide for one line" is not a reason to drop the qualifier.
     one_diagnostic() beside it already escalates 1 -> 2 -> 3 lines and
     skips only when nothing fits.

The WHERE path now routes through one_diagnostic(). There is ONE
DISPLAY renderer, so the two paths cannot diverge again.

================================================================================================

# LOCATION: converter/generators/cursor_paragraph/cursor_paragraph_body_builder.py
# ACTION: REPLACE ENTIRE FILE
"""Builds the COBOL body of a cursor OPEN / FETCH / CLOSE paragraph.

This class owns no COBOL layout literals: every token, indent and
template lives in rules/cursor_paragraph_rules.py. Only dynamic values
(cursor name, paragraph name, host variables) are substituted here.

REFACTOR - one 600-line class became six collaborators.

    cursor_line_geometry.py      does a body line fit the window
    cursor_host_reference.py     one host parser, three spellings
    cursor_key_diagnostics.py    the row-identity DISPLAY lines
    cursor_sql_location.py       MOVE ... TO SQL-LOCATION
    cursor_error_branch.py       WHEN OTHER through the period
    cursor_statement_blocks.py   header, EXEC SQL wrapper, INTO

The public surface is UNCHANGED - open_paragraph, fetch_paragraph,
close_paragraph, sqlcode_error_tail, sql_location_move,
sql_location_body and fetch_into_lines all keep their signatures, so no
caller or test moves.

CORRECTION 1 - the FETCH error branch emitted an UNQUALIFIED host.

See cursor_key_diagnostics.py. Briefly: a foreign-key column keeps the
PARENT's column name, so the data-name exists in two DCLGEN groups and
the bare form is a not-unique reference the compiler rejects. There is
now ONE DISPLAY renderer for both diagnostic paths.

CORRECTION 2 - the refactor DROPPED the fetched-column fallback.

fetch_paragraph() forwarded `where_conditions` and nothing else. A
cursor with no resolved WHERE therefore reached ErrorBranchBuilder with
both key lists empty and produced

    WHEN OTHER
         MOVE 720    TO SQL-LOCATION
         DISPLAY 'ERROR WHILE FETCHING CURSOR DZBFASC1'
         PERFORM SQLERROR

an error branch that identifies NO ROW AT ALL. The operator gets a
cursor name and nothing to look the failure up by.

Three cases, decided here and nowhere else:

    PARENT cursor      cursor name only. It is the driver; there is no
                       driving key to report. This is what the manual
                       reference shows at 720-FETCH.
    CHILD, WHERE known report the driving key - the manual reference
                       shape at 820-FETCH.
    CHILD, no WHERE    report the leading FETCHED columns, so the row
                       is still identifiable.
"""

"""Generates DB2 cursor OPEN / FETCH / CLOSE paragraphs.

This class is a FACADE. It owns orchestration only:

- resolve the cursor specs (from Db2InfrastructureGenerator)
- normalise legacy SQL-ERROR references and rewrite PERFORM targets
  (CursorPerformRewriter)
- render each paragraph body (CursorParagraphBodyBuilder)
- insert the assembled block into the program once
```

```
Paragraph LAYOUT belongs to CursorParagraphBodyBuilder, not here. Banners,
debug trace lines, join-key diagnostics and counter increments are body
concerns and must be added there.

Public interface consumed by orchestration/conversion/conversion_pipeline.py:

    converted_cobol, messages = generator.apply(
        cobol_text=converted_cobol,
        operations=operations,
    )

Do not rename or remove `apply`.

# ACTION: CREATE NEW FILE
"""Renders one DECLARE CURSOR statement.

Clause order is fixed by SQL and by the manual reference:

    SELECT, FROM, WHERE, ORDER BY, FOR READ ONLY, QUERYNO

REFACTOR - one 600-line class became five collaborators:

    declare_diagnostics.py       the decision record
    declare_operand_parser.py    column out of a free-text fragment
    declare_column_ownership.py  what does this table own
    declare_order_by_planner.py  which ORDER BY entries survive
    declare_clause_renderer.py   layout
    declare_refusal.py           the DB2 WARNING blocks

build() now reads as the sequence of decisions it is. The seventeen
corrections this file accumulated live beside the code each one fixed,
so a reader of the ORDER BY planner sees the ORDER BY history and
nothing else.

The public surface is UNCHANGED: build(spec) -> list[str], reset(), and
a messages list.

Clean Architecture:

- Every COBOL / SQL literal lives in rules/cursor_declaration_rules.py
  and rules/db2_infrastructure_rules.py.
- No regex is defined in this package.
- No program, record, table, cursor or host variable name is hardcoded.

"""Reads the COLUMN out of a free-text SQL fragment.

Two readers, one vocabulary:

    left_operand('NR_ID = :DCLG.NR-ID')  -> 'NR_ID'
    order_by_column('NR_ID DESC')        -> 'NR_ID'

CORRECTION - the parser understood SYMBOLS only.

A predicate with a KEYWORD operator carries no = < > character:

    DA_CRFMAS_479BFAS IS NOT NULL
```

```
    NR_ID_479BFAS BETWEEN :H1 AND :H2
    CO_ID_479BFAS IN (:H1, :H2)
    NM_ID_479BFAS LIKE :H1

so the WHOLE predicate came back as the "column", failed the ownership
test, and a perfectly valid cursor was refused with a DB2 WARNING. The
first operand token is taken instead, whichever operator form follows.

CORRECTION - a QUALIFIED operand never matched. T.NR_ID and NR_ID are
the same column; only the bare name is compared.

No regex. Every literal comes from rules/cursor_declaration_rules.py.

# ACTION: CREATE NEW FILE
"""Decides which ORDER BY entries survive into the declaration.

GOVERNING RULE: the converter may REFUSE to generate a clause it cannot
resolve. It must never DELETE one that has been resolved.

A generated declaration once carried

    ORDER BY CT_RKTGDSV_479BFAS
           , FILLER            <- COBOL placeholder
           , NR_ID_479BFAS DESC

FILLER is not a DB2 column, so the DECLARE bound as SQLCODE -206 and
the program never ran. One bad entry never loses the whole ordering.

CORRECTION - a duplicate was reported with the WRONG REASON.

The dedup pass logged "order_by_column_dropped", whose text reads
"... is not a column of {table}". The column IS a column of that table;
it is simply already ordered. A diagnostic that states a false cause
sends the reader to the DCLGEN instead of the ORDER BY resolver.

CORRECTION - ENFORCE_ORDER_BY_DEDUPLICATION existed and nothing read
it, the same defect class that left ENFORCE_WHERE_COLUMN_OWNERSHIP
unreachable.

"""Builds the DB2 WARNING block emitted in place of a refused cursor.

CORRECTION - the warning did not fit a COBOL line.

The single-line templates rendered to ~77 characters with real names.
The body window is columns 8-72, so the fixed-format composer wrapped
or truncated the one comment that explains why a cursor is missing.
The rules-owned *_LINES tuples are sized for the window.

CORRECTION - two refusals were SILENT.

A spec with no cursor name, or no table, emitted a warning into the
COBOL and logged nothing, so the cursor vanished and the conversion
report did not say why. Every refusal reports now.

FILE: converter\generators\db2_infrastructure\infrastructure_block_builder.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/generators/db2_infrastructure/infrastructure_block_builder.py
# ACTION: REPLACE ENTIRE FILE

"""Assembles the generated DB2 infrastructure DATA DIVISION block.

Assembly order only. Every element is rendered by a focused builder:

  1. Infrastructure marker            comment_block
  2. SQLERRWS / SQLCA / DCLGEN        IncludeRenderer
  3. SQL-LOCATION                     SqlLocationBuilder  (off by default)
  4. Cursor end-of-cursor flags       CursorFlagBuilder
  5. Cursor DECLARE statements        CursorDeclareBuilder
```

```
CORRECTION - duplicate DZBFARTV include
---------------------------------------
This builder rendered its own include statements as a three-line block,
while the update postprocess rendered a single-line form and scanned for
only that shape. It therefore did not recognise the block already
present and injected DZBFARTV a second time. A duplicated DCLGEN include
duplicates every data-name in the group, which the compiler rejects.

Include emission AND detection now go through IncludeRenderer, so one
shape and one duplicate test serve every caller.

CORRECTION - generated blocks sat in Area A
-------------------------------------------
Lines were emitted with no indent, so after fixed-format sequencing
EXEC SQL and END-EXEC landed at column 8. CHK-06.07 requires column 12.
Indents now come from rules/db2_infrastructure_rules.py.

CORRECTION - duplicate SQL-LOCATION
-----------------------------------
See sql_location_builder.py. SQLERRWS owns the field.

Clean Architecture
------------------
- Section titles and include names: catalogs/output_sections.py
- Indents, tokens and templates:    rules/db2_infrastructure_rules.py
- No regex here.
- No program, record, table, cursor or host variable name hardcoded.

ENCODING: utf-8
================================================================================================

# LOCATION: converter/generators/db2_infrastructure/spec_builder/cursor_spec_builder.py
# ACTION: REPLACE ENTIRE FILE
"""Builds cursor specifications from IDMS operations.

REFACTOR - one 380-line class became six collaborators:

    spec_fixed_format.py          columns 8-72 of a record
    spec_navigation_scanner.py    navigated / materialised records
    spec_lrf_scanner.py           LRF expansion markers
    spec_where_builder.py         relationship -> predicates
    spec_select_augmenter.py      the columns a cursor must expose
    spec_reporter.py              include names, spec diagnostics

Regex moved to patterns/cursor_spec/, constants to rules/cursor_spec/.

CORRECTION 1 - is_parent_cursor read a PARAGRAPH NUMBER.

    return fetch_paragraph.split("-")[0][0] == "7"

CURSOR_OPEN_NUMBERS is (710, 810, 910), so the THIRD cursor opens at
910 and the test returned False for it. That cursor was mis-classified
as a child and cursor_paragraph_body_builder emitted driving-key
DISPLAY lines for a cursor that has no driving key.

A cursor is a CHILD when it carries WHERE predicates and the DRIVER
when it does not - the shape the manual reference shows, and immune to
the numbering.

CORRECTION 2 - the LRF branch appended the SAME predicates twice.

    lrf_info = lrf_cursors[record_name]   <- assigned, never read
    where_conditions.extend(...)          <- the identical list

Predicates are built ONCE, by SpecWhereBuilder, which de-duplicates.
The LRF marker is REPORTED, not used as a second reason to append what
is already there.

CORRECTION 3 - a skipped WHERE was silent. A sweep cursor and a
deliberately unqualified cursor looked identical in the report.

CORRECTION 4 - the reporter was constructed EAGERLY.
```

```
    self.reporter = SpecReporter(owner.line_utils)

SpecReporter needs owner.line_utils, but ONLY include_names() ever uses
it. Reading it in __init__ silently widened the owner contract: a
caller that only augments specs - which is what
tests/test_cursor_select_column_parity.py supplies - broke at
construction with AttributeError before a single spec was touched.
Built on first use, so the constructor asks for nothing it does not
need.

"""Reads the generated LRF expansion comments back out of the program.

LrfPathExpander rewrites Logical Record Facility syntax into classic
IDMS and leaves a marker comment behind. This scanner recovers which
records came from an LRF path, so the spec builder can report it.

CORRECTION - the continuation was matched against the RAW record.

    record_match = re.search(r"\\*?\\s+(\\w+)", next_line)

ran on the un-stripped line, so the sequence number was inside the
search space. It happened to work on '002220*  VMBEVEF' because two
spaces follow the indicator, and would capture the wrong token the
moment a shop wrote '002220*VMBEVEF'. Every line is reduced to its body
first, exactly like every other scan in this package.

"""Adds the columns a cursor must project but usage analysis missed.

A minimal usage-driven SELECT can still omit two kinds of column that
the cursor is nonetheless required to expose:

  1. ORDER BY columns of the same cursor.
  2. Parent join columns referenced by a CHILD cursor's WHERE. The child
     filters on the parent host variables, so the parent FETCH must
     populate them, which means the parent SELECT must list them.

Without (2) the parent host variables stay empty and the child
predicate is evaluated against blanks - a correctness bug, not a
cosmetic one.

FETCH host variables are re-resolved for every spec whose SELECT grew,
because SELECT and INTO are kept synchronized BY POSITION.

"""Turns a resolved relationship into WHERE predicates, once.

CORRECTION 1 - the LRF branch appended the SAME predicates twice.

    if record_name in lrf_cursors:
        lrf_info = lrf_cursors[record_name]        <- assigned, never read
        if relationship and relationship.conditions:
            where_conditions.extend(               <- the identical list
                self._where_conditions_from_relationship(
                    relationship.conditions))

When the parent was also navigated, where_conditions already held those
predicates, so the clause came out as

    WHERE A = :G.A AND A = :G.A

CursorDeclareBuilder._conditions() de-duplicates byte-identical strings,
so the defect was INVISIBLE - masked by a guard in a different class,
and only while both renderings stay character-for-character equal.
Predicates are built ONCE and the LRF marker is reported, not re-used.

CORRECTION 2 - the parent table was INFERRED from the group name.

    table = dcl_name[3:] if dcl_name.startswith("DCL") else dcl_name
```

```
DclgenRepository.group_for_table() is the authority. Stripping three
characters off a name is the same class of inference that produced a
withdrawn SQLCODE -206 diagnosis earlier in this project. The
repository is consulted first; the prefix rule survives only as a
reported fallback.

"""
INITIALIZATION CENTRALIZER

Consolidates DCLGEN INITIALIZE statements into a single 100-INITIALIZE
paragraph performed once at startup.

Invariants:
  - The paragraph is CREATED and PROVEN before anything is removed. A
    half-applied pass leaves the program fetching into host groups that
    were never cleared, which is silent data corruption rather than a
    compile error.
  - An anonymous mainline is never captured. A PROCEDURE DIVISION whose
    first statement carries no paragraph header would otherwise be
    absorbed by the inserted header, taking STOP RUN with it.
  - Nothing is ever replaced by an explanatory comment. Generated
    comments are written into columns 8-72 and truncate mid-word.
    Decisions go to self.messages.
```

```
  - All matching is done against the logical body (columns 8-72), so
    fixed-format right sequence numbers cannot defeat a pattern.

================================================================================================
FILE: converter\generators\lrf_host_variable_populator.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/generators/lrf_host_variable_populator.py
# ACTION: CREATE NEW FILE
"""Generates host variable population code for LRF-expanded cursors.

PROBLEM
-------
When LRF path expansion converts "OBTAIN WHERE <keyword>" to classic IDMS,
the transformer loses the data flow context. The cursor is opened with empty
host variables, so WHERE clauses filter incorrectly.

Example from VM7BD200:
  *DB2: Expanded LRF FIRST VMBTL03-R01 WHERE SWEEP-VMBFAS -> VMBFAS
    PERFORM 710-OPEN-DZBFASC1.

The VMBFAS cursor's WHERE clause references parent archive dates, but
DCLDZBFASTV host variables are never populated.

SOLUTION
--------
This module:
1. Scans generated COBOL for "*DB2: Expanded LRF" markers
2. Extracts LRF metadata (keyword, parent record, target record)
3. Generates MOVE statements to populate host variables from parent record
4. Inserts code before PERFORM OPEN-<cursor>

GENERATED CODE PATTERN
----------------------
For cursor DZBFASC1 with parent VMBFAS:

    INITIALIZE DCLDZBFASTV.
    MOVE DA-ARCH-YMD OF VMDZ270I-REC TO DA-CCYYMMDD.
    MOVE CORR DA-CCYYMMDD-R    TO DA-DD-MM-CCYY.
    MOVE DA-DD-MM-CCYY         TO WS-DA-ARCH-YMD.
    MOVE WS-DA-ARCH-YMD        TO DA-CPTAFS-479BFAS OF DCLDZBFASTV.
    MOVE WS-DA-ARCH-YMD        TO DA-CRFMAS-479BFAS OF DCLDZBFASTV.
    PERFORM 710-OPEN-DZBFASC1.

MAPPING DATA FLOW
-----------------
Host variable population needs to bridge IDMS parent record data to
DB2 host group fields. This requires:

1. Parent record field names (from LRF metadata)
2. Host group structure (from DCLGEN)
3. Data mapping (which parent fields -> which host fields)
```

```
Current implementation reconstructs the data flow from:
- LRF expansion comment markers
- Relationship metadata in path resolver
- DCLGEN-derived host variable structure
"""

"""
PROCEDURE DIVISION ORGANIZER

Structures PROCEDURE DIVISION with proper flow and standard paragraphs.

Purpose:
  - Ensures standard paragraph flow: 100→200→300→400→500→STOP RUN
  - Creates proper initialization (100-INITIALIZE) called first
  - Creates standard paragraph structure
  - Adds 600-GET-TIMESTAMP (generic, same in all programs)
  - Creates 500-DISPLAY-TOTALS for audit trail
  - Organizes existing paragraphs under proper flow

Standard Flow:
    PROCEDURE DIVISION.
        PERFORM 100-INITIALIZE.
        PERFORM 200-OPEN-CURSORS.
        PERFORM 300-MAIN-PROCESSING.
        PERFORM 400-CLOSE-CURSORS.
        PERFORM 500-DISPLAY-TOTALS.
        STOP RUN.

    100-INITIALIZE.
        [initialization logic]
        PERFORM 600-GET-TIMESTAMP.

    200-OPEN-CURSORS.
        [open cursor paragraphs]

    300-MAIN-PROCESSING.
        [fetch and process loops]

    400-CLOSE-CURSORS.
        [close cursor paragraphs]

    500-DISPLAY-TOTALS.
        PERFORM 600-GET-TIMESTAMP.
        DISPLAY 'Program ended at...'
        DISPLAY 'TOTAL RECORDS...'

    600-GET-TIMESTAMP.
        [Generic - same in all programs]
        MOVE FUNCTION CURRENT-DATE TO TS-SYSTEM.
        [8 more MOVE statements]

Usage:
    organizer = ProcedureDivisionOrganizer(program_text)
    organized = organizer.organize()

# LOCATION: converter/generators/sql_error_generator.py
# ACTION: REPLACE ENTIRE FILE

"""Generates and ensures the SQLERROR routine.

Generic rule:
- Use SQLERROR, not SQL-ERROR.
- Generated DB2 cursor paragraphs and SQL blocks perform SQLERROR.
- The SQLERROR routine wraps the standard DB2 SQLERROR include.

Generated routine (manual reference layout):

    * SQLERROR ROUTINE.
         EXEC SQL
              INCLUDE SQLERROR
         END-EXEC.

Paragraph-header policy (Decision D-1, CLOSED by the manual reference):
- The SQLERROR copybook supplies the paragraph label itself.
- Emitting a local "SQLERROR." header duplicates that label and the
  compiler rejects the program with a duplicate paragraph-name error.
- review/standards/cobol_standards.py records the same decision:
      SQL_ERROR_BODY    = ("EXEC SQL", "INCLUDE SQLERROR", "END-EXEC")
      SQL_ERROR_INCLUDE = "INCLUDE SQLERROR"
  and CHK-05.01 accepts "declared OR included".
```

```
- Set EMIT_SQL_ERROR_PARAGRAPH_HEADER = True in rules/sql_error_rules.py
  if a site ever needs the old behaviour back.

COBOL termination rule:
- A period inside EVALUATE terminates the COBOL *sentence*, which closes
  the EVALUATE early and orphans END-EVALUATE (compile error).
- This class therefore renames SQL-ERROR to SQLERROR but NEVER adds,
  moves or removes a period on a PERFORM inside an EVALUATE block. The
  original terminator is captured by the pattern and carried through
  unchanged.

Clean Architecture:
- No regex is defined in this file. Every pattern lives in
  patterns/cursor_paragraph_patterns.py and patterns/db2_patterns.py.
- Every literal lives in rules/sql_error_rules.py.

"""
WORKING-STORAGE ORGANIZER

Organizes all WORKING-STORAGE declarations into 10 standard sections
with clear separators and proper ordering.

Purpose:
  - All declarations organized logically by purpose
  - Clear section separators for readability
  - Consistent ordering across all programs
  - Audit fields (counters, timestamps) always present
  - Production-ready code organization

Standard 10-Section Organization:
  1. CONTROL-FIELDS      (CS-PROGRAM, program ID, etc.)
  2. COUNTER-FIELDS      (WS-NB-*-COUNT for audit)
  3. TIMESTAMP-FIELDS    (TS-SYSTEM, TS-TIMESTAMP)
  4. DATUMVELDEN         (Date work fields)
  5. DATE-CONVERSION-HELPERS (HELP-* fields)
  6. FLAGS               (Status flags, switches)
  7. WORK-FIELDS         (Temporary work variables)
  8. PARAMETER-DATA      (Parameter/external data)
  9. IMPORTED-SECTIONS   (COPY statements)
  10. DCLGEN-GROUPS      (SQL INCLUDE statements)

Usage:
  organizer = WorkingStorageOrganizer(program_text)
  organized = organizer.reorganize()
"""

class ConversionComponentFactory:
    """Builds repositories, resolvers, generators, transformers, composers.

    CORRECTION 1 - module imported where an instance was required
    ------------------------------------------------------------
    This file previously carried BOTH

        from converter.resolvers import cursor_name_resolver
        from converter.resolvers.cursor_name_resolver import CursorNameResolver

    and returned the first of those under the "cursor_name" key. That put a
    MODULE into the resolver map, so Db2InfrastructureGenerator failed at
    runtime with

        AttributeError: module 'converter.resolvers.cursor_name_resolver'
        has no attribute 'cursor_name_from_table'

    The module import is removed. "cursor_name" now holds a constructed
    CursorNameResolver, like every other resolver in the map.

    CORRECTION 2 - COMMIT emitted in a read-only program
    ----------------------------------------------------
    IDMS FINISH closes the run unit, so the DB2 equivalent in an UPDATE
    program is COMMIT. A RETRIEVAL program declares every cursor
    FOR READ ONLY and has nothing to commit; the COBOL team's manual
    reference emits none, and rules/manual_reference_rules.py already
```

```
declared EMIT_COMMIT_IN_RETRIEVAL = False. Nothing read it, so
VM7BD200 shipped with

    MOVE 'COMMIT' TO SQL-LOCATION.
    EXEC SQL
      COMMIT
    END-EXEC.

The program KIND is now classified ONCE, from the SOURCE program, and
published to the two components that need it:

  1. IdmsStatementTransformer  - suppresses the FINISH -> COMMIT
                                 conversion at the point of decision.
  2. RetrievalCommitCleanupComposer - safety net for a COMMIT that
                                 arrives by any other route.

Classification reads the SOURCE, never the generated text: a generated
COMMIT would otherwise classify the program that produced it.

FAIL-SAFE: when the source is unknown (a caller that builds composers
without ever calling _repositories), the program is treated as an
UPDATE program and the COMMIT is KEPT. Removing a COMMIT a program
needs is a data-integrity defect; keeping one it does not need is a
cosmetic divergence.

LRF (Logical Record Facility)
-----------------------------
LRF metadata is OPTIONAL. With no subschema supplied, LrfRepository is
empty, LrfPathResolver reports is_empty(), and LrfPathExpander returns
the program source unchanged - so a program without logical records
converts exactly as it did before LRF support existed.
"""

    ConversionLayoutSteps,
)
```

```
from converter.generators.converter_pipeline_integration import (
    ConverterEnhancementPipeline,
)

class ConversionLayoutPipeline:
    """Runs the layout and finishing passes, in a fixed, load-bearing order.

    Pass-ordering contracts
    -----------------------
    2. ``fixed_format`` sequences every line, including generator-inserted
       blocks. It runs BEFORE any comment is emitted, so comment lines
       cannot be collapsed - at this point they do not exist yet.

    3. ``OutputWriteParagraphComposer`` extracts the record-population body
       into its own ``WRITE-<record>`` paragraph and replaces it with a
       PERFORM plus the output counter increment. It MUST run after:

         - the content phase's OutputWritePlacementCleanup, otherwise it
           extracts from the wrong paragraph and bakes in the
           once-per-child-row defect;
         - ``fixed_format``, otherwise it has no sequence area to clone
           when building the new paragraph header.

    4. ``LateDb2DateComposer`` re-runs the DB2 date and INITIALIZE passes.
       Those live inside ``feedback_cleanup`` and have already finished by
       the time step 3 moves the block into a brand new paragraph, so
       without this second run a DB2 date host field is moved straight into
       the output record, skipping the CCYYMMDD realignment. That is silent
       data corruption, not a formatting defect. Idempotent: a converted
       move carries no DCLGEN qualifier and cannot match again.

    5. ``CounterDeclarationComposer`` declares every ``WS-NB-*-COUNT`` the
       PROCEDURE DIVISION increments but WORKING-STORAGE does not define,
       and appends the end-of-run totals before STOP RUN. It MUST run after
       step 3, which is what emits the increment, and BEFORE step 7 so the
       generated DISPLAY lines are indented with everything else.

    6. ``UnmappedRecordBlockComposer`` comments record-level blocks that
       have no usable DB2 column mapping. Runs after every content pass so
       it never comments code another pass still needs to read.

    6b. ``StructuralSafetyComposer`` is the LAST guard before indentation.
       It comments whole-record references whose IDMS layout no longer
       exists, and statements left unreachable after a paragraph EXIT.
       It MUST run after step 6 - an unmapped-record block is commented
       first, so the safety pass never re-comments the same lines - and
       BEFORE step 7, so its comment lines are indented with everything
       else.

    7. ``ProcedureIndentNormalizer`` re-anchors Area B, covering the
       paragraph created in step 3, the totals added in step 5 and the
       comments added in step 6b.

    8. ``FinalSequenceResequencerService`` rewrites columns 1-6 and 73-80,
       correcting the placeholder sequence numbers cloned in steps 3, 5
       and 6b.
    """

================================================================================

# LOCATION: converter/pipeline/conversion/conversion_layout_steps.py
```

```
# ACTION: REPLACE ENTIRE FILE
"""Individual finishing passes of the IDMS->DB2 conversion.

One method per pass. Each takes the converted text, runs one composer,
drains that composer's diagnostics into the shared message list, and
returns the new text. No method knows about any other method, so the
ordering contract lives entirely in ConversionLayoutPipeline.

Deliberately NOT a mixin: it receives the composers and resolvers it
needs plus a message-collection callable, so every pass can be
constructed and tested without the component factory.

ORDERING CONTRACT (enforced by ConversionLayoutPipeline)

2.  ``apply_layout`` runs the formatter, manual layout, style preserver
    and fixed-format passes. ALL lines are sequenced here, BEFORE any
    commenting pass, so generator-inserted blocks carry a real sequence
    area and comment lines cannot be collapsed - they do not exist yet.

3.  ``OutputWriteParagraphComposer`` lifts the record-population body
    into its own WRITE paragraph. Runs AFTER fixed_format so every
    generated line can clone a real sequence area.

4.  ``LateDb2DateComposer`` re-runs the DB2 date and INITIALIZE passes.
    Those live inside ``feedback_cleanup`` and have already finished by
    the time step 3 moves the block into a brand new paragraph, so
    without this second run a DB2 date host field is moved straight into
    the output record, skipping the CCYYMMDD realignment. That is silent
    data corruption, not a formatting defect. Idempotent: a converted
    move carries no DCLGEN qualifier and cannot match again.

4b. ``RecordMaterialisationComposer`` expands every whole-record MOVE
    into a real layout plus field-by-field moves. Runs AFTER step 2 so
    generated lines can clone a real sequence area, BEFORE step 5 so the
    counter pass sees the final field list, and BEFORE steps 6 and 6b,
    which would otherwise comment the move as an undefined data-name.

5.  ``CounterDeclarationComposer`` declares every ``WS-NB-*-COUNT`` the
    PROCEDURE DIVISION increments but WORKING-STORAGE does not define,
    and appends the end-of-run totals before STOP RUN. It MUST run after
    step 3, which is what emits the increment, and BEFORE step 7 so the
    generated DISPLAY lines are indented with everything else.

6.  ``UnmappedRecordBlockComposer`` comments record-level blocks that
    have no usable DB2 column mapping. Runs after every content pass so
    it never comments code another pass still needs to read.

6b. ``StructuralSafetyComposer`` is the LAST guard before indentation.
    It comments whole-record references whose IDMS layout no longer
    exists, and statements left unreachable after a paragraph EXIT.
    It MUST run after step 6 - an unmapped-record block is commented
    first, so the safety pass never re-comments the same lines - and
    BEFORE step 7, so its comment lines are indented with everything
    else.

7.  ``ProcedureIndentNormalizer`` aligns every PROCEDURE DIVISION
    statement line to Area B.

8.  ``FinalSequenceResequencerService`` re-sequences ONLY columns 1-6
    and 73-80.

9.  Final comment cleanup. MIGRATED to converter/pipeline/registry.py
    under the stage name 'cleanup_final_comments'. The method below is
    retained as the call site so ConversionLayoutPipeline.finish() is
    unchanged; it now delegates to run_pipeline().

CORRECTION - step 4b was a silent no-op

    materialise_records returned the source unchanged and said nothing
    when the composer was absent, so an unwired feature was
    indistinguishable from a feature that ran and found nothing to do.
    The absence is now reported.

from converter.domain.models import ConversionInput
from converter.pipeline.conversion.conversion_layout_pipeline import (
    ConversionLayoutPipeline,
)
from converter.pipeline.run import run_stage
from converter.pipeline.stage import Document
from converter.validators.mapping_scope_filter import (
    MappingScopeFilter,
)
from converter.validators.mapping_validator import MappingValidator

class ConversionPipeline:
    """Runs the CONTENT phase of the IDMS->DB2 conversion.

    Depends on the host class for the component factory methods and message
    helpers (via mixins). Returns (converted_cobol, operations,
    dclgen_repository); validation messages are appended to the passed-in
    list.

    The FINISHING phase - layout, paragraph extraction, counters, indent and
    resequencing - lives in ConversionLayoutPipeline. That split keeps the
    two concerns testable in isolation: this class decides WHAT the program
    says, that class decides HOW it is laid out.

    Pass-ordering contracts (content phase)
    ---------------------------------------
    0a. ``LrfPathExpander`` rewrites Logical Record Facility syntax into the
        classic IDMS syntax the rest of the converter already understands::
```

```
        OBTAIN FIRST <LR> WHERE <keyword>  ->  OBTAIN FIRST <rec> WITHIN <set>
        LR-STATUS = 'X-EOA'               ->  DB-END-OF-SET
        FIELD OF <rec> OF LR              ->  FIELD OF <rec>
```

    It MUST run first, because MappingScopeFilter, CobolTransformer and
    ProgramFlowAnalyzer all read the source text. Every pass after this
    point sees classic IDMS and needs no logical-record knowledge.

0b. ``MappingScopeFilter`` rescopes the mapping validation report to the
    program being converted. MappingValidator audits the WHOLE Sheet
    Mapping workbook, so a restart-table gap was reported as a blocking
    error against every retrieval program that never touches it. A gap
    stays an error for a table this program references, and becomes a
    workbook note for any other.

1. ``feedback_cleanup`` (CobolCleanupComposer) runs
    ``OutputWritePlacementCleanup``, which lifts a guarded output WRITE
    out of the child-row paragraph into the PARENT paragraph, after the
    child cursor CLOSE. Left in the child-row paragraph the WRITE fires
    once per fetched child row instead of once per parent row.

Steps 2 through 8 are owned by ConversionLayoutPipeline and documented
there.

REGISTRY MIGRATION

Passes marked MIGRATED below are defined in
converter/pipeline/registry.py and executed through run_stage(). The
composer is constructed by the registry, not taken from the factory
dict. Call POSITION is still owned by this file; once every pass has
moved, ConversionLayoutPipeline.finish() collapses to a single
run_pipeline() call and the registry owns order as well.

OBSERVED DUPLICATE CALLS (behaviour preserved, not yet changed)
----
  * ``update_restart_skip`` runs twice: once after statement
    transformation and again in the cleanup group.
  * ``cursor_order_cleanup`` runs twice inside
    ``_apply_db2_infrastructure``.
Both composers are idempotent, so output is unaffected. The duplication
was invisible while each call constructed its own composer; the registry
makes it explicit. Removing either call is a separate, baselined change.

"""LRF Cursor WHERE Clause Fix - Production Deployment Guide

This module provides factory functions and configuration to deploy the LRF
cursor WHERE clause generation fix into the conversion pipeline.

The fix addresses three critical issues found in VM7BD200, VM4BD310, VM4BD302:
1. Missing WHERE clauses in LRF-expanded cursors
2. Incomplete column selection (missing key columns)
3. Incorrect ORDER BY direction (ASC instead of DESC for NEXT operations)

INTEGRATION STEPS:
1. Import: from lrf_cursor_fix import setup_lrf_cursor_where_resolution
2. Call in pipeline initialization: setup_lrf_cursor_where_resolution(owner)
3. No changes needed to existing pipeline code
"""

FILE: converter\pipeline\registry.py
ENCODING: utf-8
================================================================================

"""THE pipeline. Order in this file IS execution order.

ADD     -> one line.      REMOVE -> delete one line.
REORDER -> move one line. DISABLE -> enabled=False.

STATUS
  [LIVE]   the owning call site delegates via run_stage(); the composer
```

```
           is constructed HERE, not taken from the factory dict
  [PARKED] registered but disabled; a direct call is still active

WARNING
  A stage whose call site delegates to run_stage() MUST be enabled.
  Disabling it makes the pass silently stop running, and the row/column
  baseline will not notice. tools/baseline.ps1 guard 3 checks the log
  for evidence that key passes actually fired.

CURRENT STATE
  All seven stages are LIVE. Every direct composer call for these passes
  has been removed from conversion_pipeline.py and
  conversion_layout_steps.py.

ORDER NOTE
  While migrating, call POSITION is still owned by the call sites, so the
  order below is documentation rather than execution order. After the
  Phase B collapse - finish() replaced by a single run_pipeline() call -
  this tuple becomes the single source of truth for order as well.

DUPLICATE CALLS (pre-existing, behaviour preserved)
  'update_restart_skip'   runs twice: after statement transformation and
                          again in the cleanup group.
  'cursor_order_cleanup'  runs twice inside _apply_db2_infrastructure.
  Both composers are idempotent. Removing either call is a separate,
  baselined change.
"""

class CopybookReferenceRenamer:
    """Renames source copybook references to their derived DB2 names.

    The DB2 copybook library ships each converted copybook under its derived
    name (the VM...BD... / VM...BZ... -> VMDZ... rule), e.g. VMBD205I becomes
    VMDZ205I and VMBZ270I becomes VMDZ270I. A converted program that still
    copies the original name fails to compile, because the old member no
    longer exists in the DB2 library.

    This pass runs for every converted program. It is driven entirely by the
    COPY statements found in the program, so no copybook, record, or program
    name is hardcoded.

    What it rewrites, for each derivable copybook the program COPYs:
      - the COPY statement itself,
      - every qualified reference (OF/IN <copybook>),
      - the "<copybook>-REC" style record name and any other hyphen-qualified
        data name built on the copybook,
      - READ ... INTO <copybook>, INITIALIZE <copybook>, MOVE ... <copybook>.

    What it never touches:
      - comment / debug / page-eject lines (indicator in column 7), so the
        historical REMARKS block stays byte-for-byte identical,
      - names that are not derivable (COPY IDMS ..., ESDATMAS, subschema and
        IDMS record names whose marker is not BD/BZ),
      - IDMS records used only with IDMS verbs (OBTAIN, STORE, MODIFY) that
        have no DB2 DCLGEN equivalent.

    The derived name is always the same length as the source name (the two
    character marker is swapped for "DZ"), so a whole-line substitution keeps
    every fixed-format column - including the sequence area - aligned.

"""
Restart logic configuration - reusable across UPDATE programs.

This module provides a configuration object to specify restart behavior
without hardcoding table names, DCLGEN names, or checkpoint fields.

All restart metadata is derived from:
1. Sheet mapping annotations (TB suffix convention)
```

```
2. Parsed DCLGEN role analysis
3. Update program context
"""

class RestartConfig:
    """
    Configuration for restart-aware UPDATE program generation.

    Purpose:
    - Centralize all restart-related settings
    - Enable reuse across different update programs
    - Maintain sheet mapping alignment (TB→TV conversion)
    - Support future customization without code changes

    Attributes:
        restart_table_name: SQL table name for checkpoints (e.g., "DZ01RSTV")
        restart_dclgen_name: COBOL DCLGEN name for checkpoint structure

        program_id_field: COBOL field name for program ID checkpoint column
        phase_field: COBOL field name for phase/run checkpoint column
        date_field: COBOL field name for date/creation checkpoint column
        status_field: COBOL field name for completion status checkpoint column
        retention_field: COBOL field name for retention days checkpoint column
        payload_field: COBOL field name for checkpoint data payload

        switch_group: WS variable group for EOF/restart switches
        help_group: WS variable group for restart record and counters
        restart_record: WS variable holding checkpoint data
        read_count: WS variable for records processed count
        restart_key: WS variable for last processed record key
        commit_counter: WS variable for commit frequency counter

        commit_frequency: Commit and checkpoint update every N records
        status_incomplete: Literal value for incomplete status (default "0")
        status_complete: Literal value for complete status (default "1")
        default_phase: Literal value for initial phase (default "1")
        retention_days: Literal value for checkpoint retention (default "7")

        para_*: Paragraph names (all 700-/800-/900-/1000-level standards)
    """

================================================================================

"""
Abstract base class for restart logic generation.

This module defines the interface that all restart logic generators must implement.
Subclasses can override methods to customize restart behavior for different programs
or COBOL dialects without affecting core framework logic.

Design Pattern: Template Method
- Base class defines overall structure (generate_all_paragraphs)
- Subclasses override individual paragraph generators
- Pipeline layer orchestrates injection into COBOL source
"""

from __future__ import annotations

from abc import ABC, abstractmethod
from typing import Optional

from converter.postprocess.restart_config import RestartConfig

class RestartLogicGenerator(ABC):
    """
    Abstract base class for generating restart-aware UPDATE program logic.
```

```
This generator is responsible for creating COBOL paragraphs that:
1. Control program restart from checkpoints
2. Query and manage restart table records
3. Save checkpoint state during processing
4. Handle restart found/not found conditions
5. Manage commit frequency and program completion

This generator does NOT:
- Modify business update logic
- Touch retrieval (SELECT cursor) logic
- Change DCLGEN include declarations
- Alter field reference mappings

Thread Safety: Not required (COBOL generation is single-threaded)

Subclass Requirements:
- Override all @abstractmethod methods
- Preserve paragraph naming conventions from RestartConfig
- Generate valid COBOL with proper indentation
- Include embedded SQL where required
- Maintain QUERYNO consistency
"""

def __init__(self, config: RestartConfig) -> None:

================================================================================
FILE: converter\postprocess\restart_logic_pipeline.py
ENCODING: utf-8
================================================================================

"""
Pipeline stage for injecting restart logic into UPDATE programs.

This module defines the pipeline integration that:
1. Detects when restart logic is needed (UPDATE program with restart table)
2. Validates restart metadata availability
3. Injects restart paragraphs at appropriate locations
4. Preserves existing business logic
5. Reports diagnostics on any skips or issues

Pipeline Design:
- Stage: Late postprocess (after business logic transformation, before final cleanup)
- Applicability: UPDATE-family programs only
- Non-destructive: Skips safely if restart metadata missing
- Ordered: Restart logic injection before final code cleanup
"""

from __future__ import annotations

from typing import Optional

from converter.postprocess.restart_config import RestartConfig
from converter.postprocess.restart_logic_generator import RestartLogicGenerator
from converter.postprocess.update_postprocess_line_utils import (
    UpdatePostprocessLineUtils,

class RestartLogicPipeline:
```

```
"""
Pipeline stage for injecting restart-aware UPDATE logic.

Responsibility:
- Apply restart control flow to UPDATE programs
- Inject checkpoint save logic in main loop
- Preserve business update logic
- Do NOT modify retrieval logic
- Do NOT touch field reference mappings

Non-applicability:
- Retrieval programs (SELECT-only, no updates)
- Programs without restart table access
- Programs with missing restart DCLGEN metadata

Diagnostics:
- Logs reason if not applicable (so user knows why skipped)
- Reports injection points (control, checkpoints, paragraphs)
- Captures SQL errors or structure issues

Thread Safety: Not required (pipeline runs single-threaded per program)

Typical Usage:
    config = RestartConfig(
        restart_table_name="DZ01RSTV",
        restart_dclgen_name="DCLDZ01RSTV",
    )
    generator = CobolRestartLogicGenerator(config)

ENCODING: utf-8
================================================================================

"""
Sheet mapping to COBOL name converter for restart logic.

This module handles the critical conversion pattern:
  Sheet Mapping (TB suffix) → COBOL DCLGEN (TV suffix)

Example: VMDZ1567 updating DZBFARTV with restart on DZ01RSTV
  Sheet Name: "DZBFAR_TB" (update table with restart support)
  COBOL DCL: "DCLDZBFARTV" (column and data structure)
  Restart Table: "DZ01RSTV" (checkpoint storage)

This converter NEVER affects retrieval logic or other unrelated tables.
It only applies to the business update table when restart is enabled.
"""

from __future__ import annotations

import re
from typing import Optional

class RestartNameConverter:
    """
    Convert between sheet mapping names and COBOL DCL names.

    Conventions:
    1. Sheet mapping uses _TB suffix (table base / with backup)
    2. COBOL DCLGEN uses _TV suffix (table variable / DCLGEN structure)
    3. Business update tables: [NAME]_TB ↔ [NAME]TV (with DCL prefix)
    4. Restart tables: DZ01RSTV (no conversion, standard naming)

    Important:
    - This converter is for the BUSINESS table (what gets updated)
    - The RESTART table is separate and does NOT use this converter
    - Retrieval tables are not affected
    """

"""DCLGEN + copybook include injection and reference scanning.

CORRECTION 1 - duplicate DCLGEN include
---------------------------------------
_existing_exec_sql_includes scanned the RAW program text with a pattern
that expects the single-line form:

    EXEC SQL INCLUDE DZBFARTV END-EXEC.

Two things defeated it.

First, InfrastructureBlockBuilder emits the three-line block form, and
after fixed-format sequencing the SEQUENCE NUMBERS sit between the
tokens:

    001080     EXEC SQL                                      01080000
    001090       INCLUDE DZBFARTV                            01090000
    001100     END-EXEC.                                     01100000

The pattern's \\s+ cannot span '01080000' and '001090', so the match
failed and DZBFARTV was reported absent.

Second, even on clean text the pattern only ever recognised one of the
two shapes this codebase emits.

The injector therefore added DZBFARTV a second time. A duplicated DCLGEN
include duplicates every data-name in the group, which the compiler
rejects. CHK-08.02 reported exactly this.

Detection now runs over LOGICAL lines through IncludeRenderer, which
recognises both shapes.

CORRECTION 2 - injected includes sat in Area A
----------------------------------------------
Injected includes came from self.generator.dclgen_include*, which
rendered them with a single leading space:

     EXEC SQL INCLUDE DZ01RSTV END-EXEC.

CHK-06.07 requires at least 4 body spaces, i.e. column 12. Emission now
goes through IncludeRenderer too, so shape and indent are decided in one
place for every emitter in the project.

Copybook COPY statements are untouched: they are not EXEC SQL includes
and have their own placement rules.

    Update-postprocess only. Does not touch retrieval.

    A DB2 DATE column (DCLGEN db2_type == DATE, stored as PIC X(10)) must
    receive its value through the DD.MM.CCYY realignment, not a raw MOVE.
    TIMESTAMP columns are NOT date columns (they receive a formatted
    TS-TIMESTAMP) and are excluded.

    Finds:
        MOVE <source> TO <DATE-host> OF <DCLGROUP>
    where <source> is a plain field (not DA-DD-MM-CCYY, not TS-TIMESTAMP,
    not a literal) and <DATE-host> is a DCLGEN DATE column, and replaces it
    with the manual conversion block.

    Guards:
    - Only DATE hosts (DCLGEN db2_type == DATE) are converted.
    - TIMESTAMP / TIME columns are excluded.
    - Audit hosts (TS-UPDATE, TS-CREATE, ID-USERID, NR-USERID) are excluded.
    - Sources TS-TIMESTAMP / CS-PROGRAM are excluded.
    - Already-realigned moves (source == DA-DD-MM-CCYY) are skipped.
    - EXEC SQL host references are never touched.
    - No program, record, table, DCLGEN, or host name is hardcoded.

================================================================================================

"""Fallback DZ01RSTV DCLGEN role when restart-table metadata is unavailable.

This generator creates a standard DZ01RSTV role when:
1. The UPDATE program type is detected
2. Restart-table DCLGEN metadata is missing/unresolved
3. But the DCLGEN include and restart paragraphs are needed

The DZ01RSTV restart table is a known production DB2 object with standard
column/field definitions. This fallback uses those production standards
to allow UPDATE programs to generate complete restart infrastructure
even when DCLGEN metadata was not supplied.

IMPORTANT: This is ONLY for fallback SQL paragraph generation.
The main program (600-RESTART-CONTROL, etc.) still requires proper
metadata-driven injection via storage_include_manager.

Design:
- No hardcoding of table/column/field names outside rules
- Fallback role is created deterministically from production standards
- If metadata becomes available later, the fallback is replaced
"""

from __future__ import annotations

from converter.postprocess.update_metadata_models import DclgenRoleInfo

def create_fallback_restart_dclgen_role() -> DclgenRoleInfo:
    """
    Create a standard DZ01RSTV DCLGEN role from production definitions.

    Returns a DclgenRoleInfo populated with production DZ01RSTV
    definitions, allowing restart paragraph generation (700-SELECT,
    700-INSERT, 700-UPDATE) to proceed even when DCLGEN metadata
    was not supplied.

    Production DZ01RSTV standard:
    - Table: DZ01RSTV
```

```
    - Include: DZ01RSTV
    - Host record: DCLDZ01RSTV
    - Columns: NM_ID_RS_PROGRAM, NB_ID_RS_PHASE, DA_CR_RS, CO_ID_RS,
               NB_DAY_RS, TE_CH_RS_DATA
    - Payload: VARCHAR with -LEN and -TEXT subfields

    This role is used ONLY for SQL paragraph generation. The INCLUDE
    statement and working-storage declarations are still handled by
    storage_include_manager with explicit rules checks.
    """

# ---------------------------------------------------------------------------
# Self-contained legacy abend-marker patterns.
#
# CORRECTION - two of these patterns could never match.
#
# They previously read:
#
#     PIC\s+X$\d+$
#
# '$' is the END-OF-STRING ANCHOR, not a literal parenthesis. "X$\d+$"
# means "literal X, then end of string, then digits, then end of string",
# which is unsatisfiable. The intended expression is "X$\d+$", i.e.
# PIC X(08).
#
# The corruption came from a PDF/OCR round trip, and the comment that
# claimed "with correct $\d+$ escaping" carried it forward. Cases (b),
# (d) and (e) in remove_legacy_restart_working_storage therefore never
# fired, and legacy abend markers were silently left in the output.
#
# All patterns match the SEQUENCE-STRIPPED logical line.

```

```
        CORRECTION - this injected the WRONG body, and injected it even
        when the copybook already supplied the routine.

        The method looked only for a local 'SQLERROR.' paragraph header.
        Under the site standard there is none: the routine arrives through

            EXEC SQL
                 INCLUDE SQLERROR
            END-EXEC.

        so the header was correctly absent, and this method then appended
        the legacy DISPLAY / CALL USERABEN body on top of it. That
        duplicated the copybook routine and made the update output
        diverge from the retrieval output. CHK-05.08 reported it.

        Two changes:

          - the INCLUDE form now counts as "already present";
          - the body comes from the shared SqlErrorGenerator, so both
            program families emit one routine.

"""
```

```
Repository wrapper for Sheet Mapping rows.

Authority:
- Sheet Mapping provides DB2 record/table names and column names.
- Source-field resolution is deterministic (COBOL identifier ->
  new_db2_field_name on the same row). No fuzzy / similarity matching.

This class is a thin facade that delegates to focused helpers:
- MappingRowQuery       (row filtering / listing)
- MappingKeyResolver    (primary / foreign / non-key columns)
- MappingColumnResolver (source->column, audit, update candidates)

    Two contributions. Contribution 2 applies ONLY when the record is
    materialised; see force_full_record below.

    1. USAGE-DRIVEN  - columns FieldUsageAnalyzer proved the original
       IDMS COBOL reads. For a non-materialised record this is the
       WHOLE answer: selecting more would over-fetch, and the site
       standard requires an explicit, minimal column list
       (cobol_standards.ENFORCE_CURSOR_EXPLICIT_COLUMNS).

    2. FULL RECORD   - every mapped DCLGEN column, merged with the
       usage columns, when force_full_record is True.

    CORRECTION - this docstring described a union that the code no
    longer performs. It previously claimed contribution 2 was always
    a superset, which made a usage-only result look like a defect.
    A non-materialised record with no proven usage legitimately
    resolves to NO columns here; cursor_spec_builder's augmentation
    pass then adds the parent key columns a child WHERE clause needs.
    Verified 10-10-2026: across all six sample programs this path
    never fires and no empty SELECT is emitted.

# LOCATION: converter/resolvers/cursor_join_resolver.py
# ACTION: REPLACE ENTIRE FILE
"""Builds child-cursor WHERE predicates from IDMS set relationships.
```

```
The left operand is always a column of the CHILD table.
The right operand is always a host reference into a PARENT DCLGEN group.

    <child column> = :<parent group>.<parent host field>

Anything that cannot be resolved on BOTH sides is dropped and reported,
never guessed. This honours CONVERSION_RULES:
"Do not fabricate DB2 SQL when Sheet Mapping metadata is missing."

CORRECTION 1 - fallback constants were never imported (NameError).
CORRECTION 2 - host_for_column() does not exist on HostVariableResolver.
               The API is host_reference_for_column() + group_for_table().
CORRECTION 3 - the fallback compared a column to its OWN DCLGEN group,
               which is not a join. The parent side is now resolved from
               the relationship, or supplied explicitly by the caller
               (LRF path keyword), or the predicate is refused.
CORRECTION 4 - the facade exposes resolve() on some paths and
               resolve_for_child_record() on others; both are tolerated.

# LOCATION: converter/resolvers/cursor_order_by_resolver.py
# ACTION: REPLACE ENTIRE FILE
"""Resolves cursor ORDER BY columns.

Parent cursors receive ORDER BY only when the Sheet Mapping explicitly
indicates order semantics. Child cursors use relationship-derived order
columns.

CORRECTION 1 - the two candidate paths validated differently
------------------------------------------------------------
A Sheet Mapping row whose DB2 column cell reads FILLER reached the SQL:

    ORDER BY CT_RKTGDSV_479BFAS
           , ...
           , FILLER
           , NR_ID_479BFAS DESC
```

```
FILLER is a COBOL placeholder, not a DB2 column: SQLCODE -206 at bind
and the program never runs. Both paths now pass through ONE gate,
_valid_order_columns().

CORRECTION 2 - a sort direction was inferred from prose
-------------------------------------------------------
Substring matching made "DESC" match inside "DESCRIPTION", and the
dedicated hint list contains the very Hopex type remark carried by the
identity key - so the column the manual reference sorts ASC was emitted
DESC, reversing the extract file. Direction inference is OFF by default
and, when enabled, reads only DESC_HINT_FIELDS and matches whole WORDS.

CORRECTION 3 - the composite CALC key was ordered in full
---------------------------------------------------------
The manual reference orders its ROOT cursor on the single identity key
ascending. A surrogate identity key is unique on its own, so the
remaining composite columns add sort cost without adding determinism.
_narrowed_order_columns() is now WIRED IN - previously it was defined
and never called, so the narrowing never happened. A record with NO
identity key keeps its full composite key: a resolved clause is refused,
never deleted.

CORRECTION 4 - diagnostics could abort the resolver
---------------------------------------------------
_log() formatted with **values. The message catalogues carry different
placeholders per producer, so one missing key raised KeyError inside the
code whose only job was to report. Formatting is now non-fatal and
template-tolerant.

No program, record, table, cursor or host variable name is hardcoded.
"""

"""Resolves WHERE clauses for LRF-expanded cursors.

When LRF expansion converts "OBTAIN WHERE <path>" to classical IDMS syntax,
it leaves a comment marker like:
    *DB2: Expanded LRF FIRST VMBTL03-R01 WHERE SWEEP-VMBFAS -> VMBFAS

This resolver extracts that information and generates the WHERE conditions
that should be applied to the resulting cursor, based on parent-child
key relationships.

Key insight: LRF OBTAIN FIRST and OBTAIN NEXT both need WHERE clauses
based on their access type (parent keys or relationship keys).

# LOCATION: converter/services/cobol_area_alignment_reflow.py
# ACTION: REPLACE ENTIRE FILE

"""COBOL Area B safe two-line reflow helper.

This module only handles long-line reflow using an existing continuation
line. It does not decide Procedure Division state or SQL state.

WHAT A CONTINUATION LINE IS
---------------------------
A fixed-format COBOL statement may continue onto the next line with NO
continuation indicator, provided the break falls on a space between two
complete words. The '-' indicator in column 7 is required only when a
word or literal is split mid-token.

This helper therefore breaks on word boundaries ONLY, and never emits a
continuation indicator.

CORRECTION - combined-budget truncation
---------------------------------------
The previous version joined the statement with its continuation fragment
and re-split the pair on EVERY call, against a fixed combined budget,
slicing the overflow off the tail:

    MOVE AM-CNSTK-479BEFF OF DCLDZBEFFTV
    TO UIT-AM-                                <- UIT-AM-CN-STOCK

Every affected pair measured exactly 60 combined body characters, with
the remainder discarded, producing undefined data names.
```

```
A two-line statement is correct COBOL. Re-splitting it was unnecessary
work, and truncating the result was destructive.

This version:

- PRESERVES the existing break. The pair is re-indented in place; the
  words are not moved.
- REBALANCES at a word boundary only when the FIRST line alone no longer
  fits columns 8-72 at its new indent.
- REFUSES - returns [] so the caller leaves both lines exactly as they
  were - whenever the pair cannot be represented.
- NEVER truncates, never splits a data name, never collapses the
  statement onto one line.
- Delegates all column arithmetic to FixedFormatLineService. No private
  copy of the geometry is kept here.

Contract preserved: try_reflow_with_next_line returns either an empty
list, or EXACTLY TWO lines replacing the two it was given. It never adds
or removes physical lines.

================================================================================================

"""
COBOL Area A / Area B alignment service.

Generic behavior:
- Does not change 80-column sequencing.
- Does not change business logic.
- Only realigns Procedure Division executable statements to Area B when safe.
- Never truncates a fixed-format COBOL body to force alignment.
- Safely reflows long two-line Procedure Division statements by using the
  existing continuation line when available.

No program names, cursor names, DB2 tables, DB2 columns, DCLGEN groups,
or host variables are hardcoded.

    def condition_end_index(self, lines: list[str], if_index: int) -> int:
        """Index of the LAST line belonging to the IF condition.
```

```
    Returns if_index when the whole condition fits on the IF line.
    Returns -1 when the condition cannot be resolved, which callers
    must treat as "refuse to extract".

    CORRECTION - a dangling operator closed the condition
    ----------------------------------------------------
    The termination test inspected only the NEXT line's first word:

        if depth <= 0 and not self._continues_condition(body):
            return index - 1

    so this four-line condition was measured as ONE line:

        IF (HELP-DA-CPTAFS-479BFAS < DA-ARCH-YMD  AND
        HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR

    Line 1 ends on AND; line 2 opens with a data-name, which is
    neither a continuation token nor "(", so the scan stopped.
    OutputWriteGuard then saw a single-line condition, allowed the
    extraction, and the IF was cut from its own condition tail.

    A line ending on AND / OR / NOT has no right operand yet. The
    condition CANNOT end there, whatever follows. This is the first
    of the three clauses in this module's own contract, and it was
    the one missing from the code.

ENCODING: utf-8
================================================================================

"""
Cursor SELECT minimizer service.

Generic behavior:
- Removes columns selected/fetched only for ORDER BY when safe.
- Does not hardcode cursor names, table names, columns, or host variables.
- Keeps SELECT and FETCH INTO synchronized by position.

Important:
- Comma normalization is scoped only to SELECT item lines between SELECT and FROM.
- FETCH comma normalization is scoped only to host variables between INTO and END-EXEC.
- SQL keywords such as WHERE, FROM, ORDER BY, and FOR READ ONLY are never
  treated as selected columns.

"""Fixed-format COBOL line helper service.

No regex.
No business hardcoding.

Purpose:
- Preserve existing left sequence, indicator, body, and right sequence layout.
- Allow services to update only the COBOL body area safely.

CORRECTION 1 - silent truncation
--------------------------------
build() previously did:

    safe_body = str(body or "")[: self.BODY_WIDTH].ljust(self.BODY_WIDTH)

which cut any body longer than columns 8-72 without telling anyone, so

    MOVE NR-IDGOOD-479EVEF OF DCLDZEVEFTV    TO WS-NR-ID-GOOD

was written out as

    MOVE NR-IDGOOD-479EVEF OF DCLDZEVEFTV    TO WS-NR-ID-GO

Truncation is never a correct outcome for COBOL source:
- build()                 raises BodyOverflowError instead of truncating.
- build_or_none()         returns None instead of raising.
- replace_body()          is total: returns the ORIGINAL line unchanged when
                          the new body does not fit.
- replace_body_wrapped()  returns one or more physical lines.

CORRECTION 2 - sequence numbers leaking into the body
-----------------------------------------------------
is_fixed_line() previously required a full 80 columns AND a numeric right
sequence:

    len(text) >= 80 and text[0:6].isdigit() and text[72:80].isdigit()

A hand-maintained member often carries a short line such as

    001690/

(7 characters, page eject, no right sequence). That failed the test, so
split() returned the WHOLE line as the body. The left sequence and the
indicator then became COBOL text, and a later terminator pass produced

    001690/.

which is not a valid COBOL statement.

A line is now fixed-format when columns 1-6 are numeric and column 7 holds
a valid indicator. The right sequence is optional. split() pads short lines
so column access is always safe.

CORRECTION 3 - partial sequence dropped
---------------------------------------
build() assembled 80 columns only when BOTH sequences were present. With the
relaxed parser a short line yields a left sequence and an empty right
sequence, so the left sequence was being discarded. build() now assembles
whenever EITHER sequence is present and pads the missing side.

CORRECTION 4 - two-line wrap ceiling
------------------------------------
wrap_body() refused any statement needing more than two physical lines, so
```

```
long generated bodies were silently skipped. wrap_body_lines() wraps into N
lines. wrap_body() keeps its original two-line contract for existing callers.

Migration note: any caller that relied on build() truncating must switch to
replace_body_wrapped() or pre-check with body_fits().

"""Generic name normalization helper.

This service contains name transformation logic only.
Regex patterns are stored in patterns/naming_patterns.py.

DEFECT FIX
----------
`normalize()` produces a DB2 identifier (hyphen -> underscore). It was
being used to render IDMS SET and RECORD names into generated COBOL
comments, which emitted

    *DB2: Converted OBTAIN FIRST VMBFAS WITHIN AR_VMBFRM1.

instead of the IDMS spelling `AR-VMBFRM1`. An IDMS set name is never a
DB2 identifier, so it must never pass through `normalize()` on its way
to output.

`to_idms_name()` is the explicit, self-documenting entry point for that
case. It is a thin alias of `to_cobol()` so the two can never drift.

"""
Update COBOL final cleanup service.

Generic behavior:
- Converts non-SQL DCLGEN dot references to COBOL OF qualification.
- Replaces residual bare IDMS record initialization with resolved DCLGEN
  group initialization when there is strong local DCLGEN context.
- Populates update audit host variables before UPDATE SQL blocks.
- Replaces generated DB2 diagnostic labels that still contain IDMS record names
  with nearby resolved DB2 table names.
- Does not hardcode program names, records, DB2 tables, DB2 columns,
  DCLGEN groups, or host variables.
"""

================================================================================================

# LOCATION: converter/services/working_storage_group_selector.py
# ACTION: CREATE NEW FILE
"""Chooses a SAFE 01 group for generated working-storage fields.

A generated counter must never be added to a record layout. Adding a
field to a fixed-length record shifts every byte after it, silently
corrupting the output file.

An 01 group is a record layout when any of these hold:

  * it is declared under FD / FILE SECTION,
  * it is the operand of WRITE / READ / REWRITE / RELEASE / RETURN,
  * it appears as WRITE ... FROM <name> or READ ... INTO <name>,
  * it is the target of MOVE SPACES / ZEROES TO <name>.

When no safe group exists the selector reports that a dedicated group
must be created. It never guesses.

# LOCATION: converter/transformers/cobol_program_id_transformer.py
# ACTION: REPLACE ENTIRE FILE
"""Target PROGRAM-ID replacement, PROGRAM-ID period cleanup, and the
PROGRAM-NAME literal rewrite.

CORRECTION 1 - three undefined names
------------------------------------
`program_name_literal_replacement` referenced
ENFORCE_PROGRAM_NAME_LITERAL, PROGRAM_NAME_LITERAL_MOVE_PATTERN and
```

```
PROGRAM_NAME_LITERAL_MESSAGES, none of which were imported. The first
call raised NameError.

The flag and the messages now live in rules/cobol_transformer_rules.py.
The pattern is MOVE_TO_PROGRAM_NAME_PATTERN, which already exists in
patterns/final_feedback_fix_patterns.py - a second, near-identical
pattern would be two definitions of one fact.

CORRECTION 2 - self.messages did not exist
------------------------------------------
The method appended to `self.messages`, which __init__ never created, so
even a successful match raised AttributeError. The list is now owned
here and cleared by reset(), which callers invoke once per program. One
component factory instance converts a whole folder, so an uncleared list
carries program 1's diagnostics into program 2.

CORRECTION 3 - the terminating period was dropped
-------------------------------------------------
MOVE_TO_PROGRAM_NAME_PATTERN captures three groups:

    prefix  = "MOVE '"
    program = "VM7BD200"
    suffix  = "' TO PROGRAM-NAME."     <- the period lives HERE

Substituting the flat string "MOVE '<target>' TO PROGRAM-NAME" discarded
the suffix, so the statement lost its period and ran into the next one.
The replacement now rebuilds from the captured groups, so whatever
terminator the author wrote is carried through unchanged.

CORRECTION 4 - group name
-------------------------
match.group("literal") - the group is named "program".

RELATIONSHIP TO ProgramNameSyncService
--------------------------------------
That service performs the same rewrite as a WHOLE-TEXT pass, reading the
FINAL PROGRAM-ID out of the converted text. This method is the PER-LINE
form and additionally refuses a literal that is not the source program
id. Run ONE of them, not both: a second pass is a harmless no-op because
the literal already equals the target, but two owners of one rule drift.

# LOCATION: converter/transformers/cobol_transformer.py
# ACTION: REPLACE ENTIRE FILE
"""Converts IDMS COBOL statements to DB2-compatible COBOL.

Responsibilities are delegated to focused helper classes while keeping the
existing public API unchanged.

CORRECTION 1 - the IDMS-ABORT paragraph BODY survived its header
----------------------------------------------------------------
The source carries

    EINDE-PROGRAMMA-EXIT.
        EXIT.
    /
    IDMS-ABORT.                     <- header
        CLOSE FORM.                 <- body
        COPY IDMS IDMS-STATUS.      <- body

Only the header was removed. CLOSE FORM was left stranded after a
paragraph EXIT, and StructuralSafetyComposer then correctly commented it
as unreachable:

    *DB2-KEEP: statement follows a paragraph EXIT and is unreachable.
    *DB2-KEEP CLOSE FORM.

The safety pass was right; the removal was incomplete. The manual
reference deletes the whole paragraph. Skipping now runs to the next
paragraph header, section header or division boundary, so no business
line can be swallowed, and a blast-radius cap reverts to normal
processing if the boundary is never found.

CORRECTION 2 - PROGRAM-NAME disagreed with PROGRAM-ID
-----------------------------------------------------
PROGRAM-ID was rewritten to the derived DB2 id while

    MOVE 'VM7BD200' TO PROGRAM-NAME.

kept the source id, so the job log and every abend message named a
program that no longer exists. The manual reference carries
MOVE 'VMDZ7200' TO PROGRAM-NAME.

ProgramNameSyncService already performs this rewrite safely - it reads
the FINAL PROGRAM-ID out of the converted text and touches only a
MOVE literal TO PROGRAM-NAME. It was simply never called. It runs as the
last pass, AFTER fix_program_id_period, so the id it reads is final.

class FieldReferenceRewriter:
    """
    Generic IDMS field reference to DB2 DCLGEN reference rewriter.

    Public facade preserved for existing callers.

    Rules:
    - Qualified references are always eligible:
        FIELD OF RECORD
        FIELD IN RECORD
    - Bare references are eligible only when active record context is strong.
    - Date fields are protected only for bare references.
```

```
CORRECTION 1 - the rewrite broke fixed-format geometry
------------------------------------------------------
_rewrite_line substituted into the WHOLE record, sequence areas
included. A qualified rewrite is almost always longer than what it
replaces:

    DA-CPTA-FORM-AS OF VMBFAS         25 characters
    DA-CPTAFS-479BFAS OF DCLDZBFASTV  32 characters

so an 80-column record became 87 and the right sequence 00002020
moved from column 73 to column 80. Later passes read the first
displaced digit as body text and emitted

    AND HELP-DA-CPTAFS-479BFAS NOT = '00000000') OR 0

Substitution now happens inside columns 8-72 ONLY, and the record is
reassembled from its own left sequence, indicator and right sequence.

CORRECTION 2 - trailing blanks were stripped
--------------------------------------------
`line = raw_line.rstrip()` removed the body padding that positions
the right sequence at column 73. Only the line ending is stripped
now; columns 8-72 keep their blanks.

CORRECTION 3 - an over-long rewrite had nowhere to go
-----------------------------------------------------
A body that no longer fits 65 columns is WRAPPED at word boundaries
onto further physical lines. _rewrite_line therefore returns a LIST,
and the caller extends rather than appends. When even a wrapped form
cannot be represented the original line is kept and reported: a
rewrite that cannot be rendered must never corrupt the record.

CORRECTION 4 - reference-map building was a tail method
-------------------------------------------------------
_build_reference_maps was the last method before __all__ and was
lost in transit, producing

    AttributeError: 'FieldReferenceRewriter' object has no
    attribute '_build_reference_maps'

rewrite() now calls the context builder directly, so no helper is
required, and the helper itself is declared next to __init__.

# ACTION: REPLACE ENTIRE FILE
"""IDMS declarative and control statement conversion.

Conversion logic only. Regex patterns live in patterns/idms_patterns.py;
all *DB2: message text lives in rules/idms_transformer_messages.py.

THIS IS A MIXIN
---------------
IdmsStatementTransformer composes it:

    class IdmsStatementTransformer(
        TransformerSharedMixin,
        ControlStatementConverterMixin,
        DataStatementConverterMixin,
    ):

The host owns construction and owns `messages`, which reset() clears once
per program. This module declares NO __init__ and NEVER rebinds
`self.messages`.

DISPATCHER CONTRACT - FOUR REGISTERED CONVERTERS
------------------------------------------------
IdmsStatementTransformer.__init__ builds a fixed table of bound methods.
Every name and arity below is a contract. Renaming one raises
AttributeError at construction; changing its parameter count raises
TypeError on the first line converted.

    (self._convert_declarative_or_control,        ARITY_UPPER_LINE)
    (self._convert_finish_or_commit,              ARITY_WITH_DIVISION)
    (self._convert_bind_ready_connect_disconnect, ARITY_WITH_DIVISION)
    (self._convert_status_abort_perform,          ARITY_WITH_DIVISION)

    ARITY_UPPER_LINE    -> (upper, stripped_line)
    ARITY_WITH_DIVISION -> (upper, stripped_line, current_division)

Declaratives are arity 2 because they are non-executable: their removal
never needs CONTINUE, so the division is irrelevant. The three executable
families are arity 3 because a removal inside PROCEDURE DIVISION must
carry CONTINUE.

RETURN CONTRACT - ONLY A NON-EMPTY RESULT COUNTS
------------------------------------------------
Per CORRECTION 2 in the host: the dispatcher treats only a NON-EMPTY list
as a conversion. None or [] falls through to the next converter, and
finally to token replacement, so a statement can never disappear without
a *DB2: comment explaining it.

PATTERN NAMING
--------------
FIND CURRENT is FIND_CURRENT_PATTERN in patterns/idms_patterns.py.
FIND_CURRENT_STATEMENT_PATTERN is a DIFFERENT name in
patterns/cobol_transformer_patterns.py, used by idms_residual_cleanup.py.

CORRECTION - COMMIT emitted in a read-only program
--------------------------------------------------
IDMS FINISH closes the run unit, so the DB2 equivalent in an UPDATE
program is COMMIT. A RETRIEVAL program declares every cursor
FOR READ ONLY and has nothing to commit; the manual reference emits none,
and rules/manual_reference_rules.py already declared
EMIT_COMMIT_IN_RETRIEVAL = False. Nothing read it.

ConversionComponentFactory publishes the policy onto the transformer
```

```
instance as `emit_commit`, classified ONCE from the SOURCE program, read
here with getattr(self, "emit_commit", True). The default True means any
caller that never sets a policy keeps the previous behaviour byte for
byte.
"""

class DataStatementConverterMixin:
    """Converts IDMS data-access statements to DB2/cursor COBOL.

    NAME HANDLING CONTRACT
    ----------------------
    Two forms of every IDMS name are needed and they must never be mixed:

        *_key      NameNormalizer.normalize()  -> DB2 identifier, underscore
                   separated. Used ONLY for resolver / repository lookups
                   and for the opened_set value returned to the caller,
                   which downstream passes re-normalize.

        *_display  NameNormalizer.to_cobol()   -> IDMS / COBOL spelling,
                   hyphen separated. Used ONLY inside generated *DB2:
                   comment text.

    CORRECTION 1 - IDMS set name emitted as a DB2 identifier
    --------------------------------------------------------
    _convert_obtain_first_next and _convert_find_first passed the
    normalized key straight into the comment template, so an LRF-expanded
    program produced

        *DB2: Converted OBTAIN FIRST VMBFAS WITHIN AR_VMBFRM1.

    for the IDMS set AR-VMBFRM1. An IDMS set is not a DB2 identifier and
    must keep its hyphens. _convert_obtain_calc already did this correctly
    via cobol_record; the other two were never brought in line.

    CORRECTION 2 - hyphenated record names were corrupted too
    ---------------------------------------------------------
    The same defect rendered record VMB-FAR as VMB_FAR. It went unnoticed
    only because the reference program's record, VMBFAS, carries no hyphen.

    CORRECTION 3 - no unmapped-record guard on the cursor paths
    -----------------------------------------------------------
```

```
_convert_obtain_calc and _convert_store_modify_erase both refuse when
table_for_record() is empty. The two cursor converters did not, so an
unmapped record resolved to an empty table, then to an empty cursor
name, and the generated lines read

    PERFORM OPEN-.
    PERFORM FETCH-.

which the compiler rejects. Both now keep and comment the statement.

CORRECTION 4 - FIND FIRST declares <record> as OPTIONAL
-------------------------------------------------------
FIND_FIRST_PATTERN allows 'FIND FIRST WITHIN <set>', which yields
record=None -> empty record -> the same broken PERFORM. Guarded.

    Conversion logic only. Regex patterns live in patterns/idms_patterns.py;
    all *DB2: message text lives in rules/idms_transformer_messages.py.
```

```
Feedback-driven rules:
- OBTAIN CALC does not generate DB2 SELECT for update flow.
- Direct UPDATE is enough when the WHERE has all composite PK/CALC keys.
- Original IDMS OBTAIN CALC is still removed from final COBOL.
- SqlGenerator methods already generate SQLCODE checks where required.
- This transformer must not add duplicate SQLCODE wrappers.

CORRECTION 1 - state leaked between programs
--------------------------------------------
ConversionComponentFactory builds ONE instance, and the batch runners
convert every program in the folder inside a single process. Because
`messages` and `unmapped_records` were only initialised in __init__,
program 1's unmapped records were still present when program 2 ran,
and the record-level composer commented records program 2 never
referenced. reset() now clears per-program state; call it once per
program, before the first transform_line().

CORRECTION 2 - an empty result deleted a statement
--------------------------------------------------
The dispatcher accepted any non-None result. A converter that returned
an empty list therefore removed the source line silently. Only a
NON-EMPTY result now counts as a conversion; anything else falls
through to the next converter and finally to token replacement, so a
statement can never disappear without a *DB2: comment explaining it.

CORRECTION 3 - the converter chain was rebuilt per line
-------------------------------------------------------
Seven closures were allocated for every source line. The chain is a
fixed table of bound methods built once in __init__.

# LOCATION: converter/transformers/lrf_path_expander.py
# ACTION: REPLACE ENTIRE FILE
"""Expands LRF syntax into the classic IDMS syntax the converter knows.

NO-LRF CONTRACT
---------------
```

```
With no logical record metadata, or with metadata but no LRF syntax in the
program, expand() returns the source text byte-for-byte. The converter
therefore behaves exactly as it did before LRF support existed.

NAME FORM
---------
Generated names are COBOL form (UPPERCASE, hyphens). NameNormalizer is not
used here: normalize() yields DB2 column form and would emit VMBTL03_R01.

COMMENT FORM
------------
A generated comment line carries '*' in the indicator column and its
marker starts immediately at column 8, so the output reads

      *DB2: Expanded LRF ...
      *DB2-KEEP: ...

which matches the marker text declared in rules/.

================================================================================================
FILE: converter\transformers\lrf_update_expander.py
ENCODING: utf-8
================================================================================================

# LOCATION: converter/transformers/lrf_update_expander.py
# ACTION: CREATE NEW FILE
"""Expands the UPDATE-side Logical Record Facility syntax into classic IDMS.

WHY THIS EXISTS
---------------
``LrfPathExpander`` teaches the converter the READ and DELETE logical-record
forms::

    OBTAIN FIRST <logical-record> WHERE <keyword>.   -> OBTAIN FIRST <rec> WITHIN <set>.
    ERASE        <logical-record> WHERE <keyword>.   -> ERASE <rec>.

The WRITE-side forms have the same shape but the converter never learned
them, so an update program written against a logical record kept its LRF
verbs all the way to the residual-IDMS checks::

    MODIFY <logical-record> WHERE <keyword>.   (SQL UPDATE)
    STORE  <logical-record> WHERE <keyword>.   (SQL INSERT)

This transformer closes that gap. It rewrites the update-side LRF form into
the classic IDMS form the rest of the pipeline already converts to DB2 DML,
and the update post-processor then supplies the WHERE key and audit columns.

NO-LRF CONTRACT
---------------
With no logical record metadata, or with metadata but no LRF update syntax in
the program, ``expand()`` returns the source text byte-for-byte. A program
that never used a logical record therefore behaves exactly as before.

MODIFY vs STORE
---------------
MODIFY is the SQL UPDATE case. The element record to modify is the record the
path makes current with its last FIND / OBTAIN navigation command - the only
element the subschema parser captures for a MODIFY path-group - so MODIFY is
expanded whenever that record resolves and is mapped.
```

```
STORE is the SQL INSERT case. A STORE path-group usually seeds several element
records the subschema does not pin down, so guessing which one to write is
unsafe. STORE is expanded only for a single-element logical record; otherwise
it is kept, with a ``*DB2-KEEP:`` audit comment, for manual review.

NAME FORM
---------
Generated names are COBOL form (UPPERCASE, hyphens). NameNormalizer is not
used here: normalize() yields the DB2 column form and would emit VMBTL07_R01.

# LOCATION: converter/ui/message_classifier.py
# ACTION: CREATE NEW FILE

"""Classifies pipeline messages into severity and category.

Pure logic: no Streamlit, no file access, no COBOL knowledge. The UI
layer renders whatever this returns.

Classification order
--------------------
1. PREFIX  - the text before the first colon. A source that only ever
             reports failures, or only ever reports normal work, is
             decided once here.
2. KEYWORD - applied only when the prefix does not decide.
3. DEFAULT - Info. Most of the list is pass narration, so an unmatched
             message is far more likely to be narration than a fault.

Deliberate default
------------------
Defaulting to Info rather than Warning is the whole point of this class.
The previous UI treated every message as a warning, which buried the two
that mattered under eighty that did not.
